Is one to conclude from Surgeon Cullimore's prefatory remarks that he has reverted to the ancient and exploded theory that "sea influences and salt provisions" *per se* are causative of scurvy? If not, whence the necessity of the statement that "the very bullocks died from want of *it* owing to the heavy salt tax" (I presume the word *it* refers to "salt," although it would be difficult to understand it to do so otherwise than from the context)? Now, I would ask whether it is not within the bounds of possibility that absence of sufficient pasturage and, occasionally, of water-supply were the proximate causes of the heavy mortality amongst bullocks which undoubtedly occurred? Again, why need he seriously ascribe the occurrence of scurvy in human beings as due "to the effects of *roots*, nuts, wild aloes, *prickly pear*, and such inedible matters"? Whence the necessity for this new theory? Is it not possible that the proximate cause of disease was the absence of sufficient vegetables and fruit in the diet of the famine stricken, depriving them of that class of salts whose acids form carbonates in the system (Parkes)? That scurvy was not due to starvation in its usually accepted sense (the remaining alternative given by him) may be inferred from the fact that I have known European officers suffer severely from the disease, resulting from absence of vegetable diet, when on tour through a district where the drought had been excessive, although they did not lack other articles of diet; secondly, from similar imperfect supply, I have seen natives monetarily in a position which would have removed them from the possibility of being famine subjects, fall victims to scurvy; thirdly, in one district in which I served, where drought was barely felt, and vegetation was therefore in fair condition—famine existing only on account of prices of grain, which necessarily ranged throughout the country,—scurvy was known only in cases imported from other districts. In short, the causation of scurvy in the Madras famine formed no exception to that found under other circumstances by hosts of observers on sea or land.

Much confusion as to the subject of starvation would be saved if the following simple plan were adhered to—namely, of regarding the term "simple starvation," divisible into an acute and chronic form, as applicable to those cases in which, from the symptoms displayed, there is no reason to believe that no constituent of human diet has been absent more than another, and of regarding the term "specific starvation" as applicable to those cases in which there is reason to believe healthy nutrition has been impaired as a result of absence of certain necessary constituents. Under such a classification scurvy would appear as a form of "specific starvation."

With regard to the experiments advanced by your correspondent to prove "the preventive and remedial effects of molasses in scurvy," I believe they simply demonstrate that if an addition of saccharine matter be made to a fairly good diet, fattening would be exhibited sooner than in its absence—not a very novel fact! If, however, Surgeon Cullimore really intends it to be understood that, consonant with increased weight, scorbutic symptoms may be expected to disappear, I can assure him this is far from being the case, and in this observation I by no means stand alone. I have seen wretchedly weak famine-stricken prisoners become decidedly fat and apparently well nourished after admission; yet, if these men's mouths were examined, the usual signs of scurvy were frequently found. Indeed, many of these "sleek" men ultimately fell victims to chest affections, dysentery, and gangrenous ulcers of scorbutic origin. In fact, my experience would lead me to infer that scurvy superadded to chronic starvation is a most intractable disease, and that increase of weight to even a large extent by no means justifies the supposition that the scorbutic taint is got rid of.

If the alleged antiscorbutic properties of molasses are derived from "partial acetous fermentation," why resort to a famine patient's stomach as a laboratory for its production! Would not such a process represent a mal-assimilation of saccharine matter? Would not such an occurrence precipitate intestinal affections in a patient so strongly predisposed as a famine subject? Finally, would Surgeon Cullimore guarantee to keep himself free from scurvy upon a diet of rice and dholl, with an unlimited allowance of jaggary? Until an experiment of the description is employed, I see little reason for believing that saccharine bodies are to be credited with any power beyond that of fat and heat formers. Performing such functions, it is possible, indirectly, that they may modify and ameliorate the effects of scurvy. But, as fatty bodies are ten and a half times more powerful in this respect, might not they be as usefully employed? If given as a cure for scurvy in a case *not complicated with simple starvation*, and remedial effects were ascertained, your correspondent might then, I think, with more confidence give jaggary the reputation of yielding "preventive and remedial effects in scurvy."

Your obedient servant,

Feb. 1880. A MADRAS FAMINE-WALLAH.

THE RADCLIFFE TRAVELLING FELLOWSHIP.

IN reference to our announcement last week that the decision of the examiners for the Radcliffe Travelling Fellowship in the University of Oxford had still to be confirmed by the electors, Mr. Wansbrough Jones writes to us saying that this is incorrect. The electors had ratified the examiners' decision before the result was announced.

T. N. D.—The questions have no medical bearing. We cannot deal with them.

OBSTETRIC ETHICS AND SYPHILIS.

To the Editor of THE LANCET.

SIR,—I should be glad if you will kindly express your opinion with regard to A.'s conduct in the following case:—

Mr. A. had been treating Mrs. B. for syphilis during two months previous and up to the time of her confinement. Mr. A. wrote to her husband, who did not reside with her, stating that on account of the malady she was suffering from he absolutely declined to attend her when in labour. The husband replied to say that he would find another doctor for the confinement. About a month ago Mrs. B.'s sister called upon me, and engaged me to attend Mrs. B. in her confinement, not mentioning anything with regard to her illness, or informing me that another medical man was attending her. The labour was natural, and in two days after I was informed that Mr. A. had been Mrs. B.'s doctor since she came to live in this neighbourhood, and that he would now go on with the case. Mr. A., with whom I am personally acquainted, was informed of my engagement two days previous to labour setting in, but he did not communicate with me. Now that the confinement is over, and also all risk of contagion, Mr. A. has resumed his attendance upon Mrs. B. I enclose my card. I am, Sir, yours &c.,

March 8th, 1880. C.

*** We cannot admire the part played in the above case by either Mr. A. or the patient and her friends. A. might have forewarned C., or, at the very least, have explained to the husband of the patient the duty of stating to C. the nature of the circumstances, and the dismissal which awaited him after the accouchement.—ED. L.

THE TREATMENT OF SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—As every contribution towards the treatment of *mal de mer* is generally welcomed, I beg to state the result of two years' experience, for the most part in the tropics. The best remedy I have found is a combination of small doses of bromide of potassium and hydrate of chloral taken with the citrate of magnesia during effervescence. Spirits of sulphuric ether may be added sometimes if there be much prostration. I may say that this remedy has only failed me in one case.

I am, Sir, yours &c.,

FREDERIC W. CORY,
Late Surgeon, Eastern and Australian Mail S. Co.

Buckhurst-hill, March 9th, 1880.

MEDICAL BENEVOLENT COLLEGE. — APPLICATION: MAY ELECTION.

To the Governors of the Royal Medical Benevolent College, Epsom.

HAMILTON GEORGE, AGED THIRTEEN YEARS,

Fourth son of the late George Smith Delavil Harris, L.R.C.P., who was in practice for many years at Leighton Buzzard, Beds, and died in September last, after a very sudden illness, brought on by overwork and anxiety, at the age of fifty, leaving a widow and ten children, seven of whom are very young, and entirely dependent upon her, and she is not in a position to educate them, being totally unprovided for through his sudden loss. The boy's age precludes him from more than two elections, so that your assistance is most anxiously asked for.

The case is strongly recommended by Prescott Hewett, Esq., F.R.S.; John Simon, Esq., F.R.S.; Lady Duncombe; Mrs. Arthur Flowers; Miss Cavendish; A. Macnamara, Esq.; Leopold de Rothschild; &c. &c.

*** We can strongly recommend this case as deserving the support of the Governors.—ED. L.

TYPHUS IN ST. PETERSBURG.

"PURPURIC" typhus is reported to have appeared in St. Petersburg. On the 22nd February a woman attacked with this disease was admitted into the clinic of Baron Villiers, under the care of Professor Botkine, and quickly succumbed. Shortly afterwards the children of the defunct, aged respectively twelve, nine, and three years, were admitted with the same illness. The disease next spread in the children's wards, where it was dominant at the time of the latest news. It is added that the symptoms at first differ little from measles, with which disease it may easily be confounded.

A Country Practitioner.—We must refer our correspondent to our advertising columns, or to an agent.

THE FLESH OF DISEASED ANIMALS AS FOOD.

To the Editor of THE LANCET.

SIR,—Let me ask you a question. You probably know that a very large number of animals nowadays, bullocks, sheep, and pigs, are found when killed to have unsound lungs or liver. In fact, I have been assured by butchers that it is quite the exception for them to kill an animal perfectly sound in lungs and liver. Sheep are this year largely affected by liver disease, and pigs are as largely affected by lung disease. What I would ask is: Do you suppose that mutton and pork from sheep and pigs so affected are injurious as food? Suppose that to all *appearance* the meat is good when the animal is cut up, do you suppose that the local disease (in lungs or liver) has rendered the meat unfit for food?

March 13th, 1880. Yours sincerely, FARMER.

Private R.V.—To prevent blisters, it is of the utmost importance to have a well-fitting boot, and to march in worsted socks. We can speak from personal experience of the value of soapin- the socks. When the feet are tender, but the skin unbroken, sponging them with spirits in many cases does good.

CROTON LINIMENT FOR "FITS."

To the Editor of THE LANCET.

SIR,—A correspondent writes to you on Croton Liniment for Fits, and at the end of the letter wishes to know how to avoid the precipitate caused by adding liq. ferr. dialysat. to a mixture. If he makes the mixture up with "distilled water," he will find it clear.—Yours truly,

March, 1880. N.

Gulstonian Lectures

ON

EPILEPSY.

Delivered before the Royal College of Physicians,

BY W. R. GOWERS, M.D., F.R.C.P.,

SENIOR ASSISTANT-PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE III.—PART I.

MR. PRESIDENT AND GENTLEMEN, — The aid which, during the last twenty years, the microscope has afforded in the investigation of the morbid anatomy of diseases of the nervous system has thrown little if any light on the pathology of idiopathic epilepsy. Neither the observations of Schrœder van der Kolk on the size of the vessels of the medulla oblongata, nor the changes which have been described by Meynert in the cornu Ammonis, can, I think, be accepted as having any real significance. In the cases I have had an opportunity of examining, the cornu Ammonis has presented no pathological change; while in two cases in which I have met with disease of this structure the patients had never suffered from convulsion. In considering, therefore, the pathology of epilepsy, we must seek for other evidence than that afforded by the pathological anatomy of the idiopathic disease, and draw our inferences from the morbid changes in organic disease attended by convulsion, and from the facts furnished by experiment and by the clinical study of the disease.

It may, in the first place, be assumed as not needing proof that the muscular spasm which constitutes the most conspicuous feature of the attack is due to the sudden violent action of nerve-cells—i. e., to the "discharge" of grey matter; and that the sensations which the patient experiences before losing consciousness are due, directly or indirectly, to the same cause—to the commencement of the discharge. To prevent misconception, I may say that the word "discharge" is used in the sense in which it has been employed by Dr. Hughlings Jackson and others, as a short expression for the sudden liberation of nerve-force, without any theory as to the form of physical or vital force thus liberated.

Premising this, the subject of the pathology of epilepsy resolves itself, in the main, into four questions, What is the seat of the discharge which thus produces the symptoms of the fit? Is the seat of the discharge the seat of the disease? How far does such discharge explain all the symptoms of the attacks? What is the nature of the morbid change which causes the discharge? Perhaps to no one of these questions can a conclusive answer be given. Nevertheless, these are facts which indicate the direction in which an answer is to be sought, and, what is equally important, the direction in which we must not seek it too exclusively.

What is the seat of the primary discharge? What grey matter is it which thus suddenly stimulates the nerve fibres and the muscles? It is hardly necessary to remark that the spinal cord acts only as a conductor, and that the over-acting grey matter is to be sought for above it, within the skull. Regarding the encephalic masses, we have two classes of facts. First, that there exist in the medulla oblongata, adjacent to the centres which regulate the respiratory movements and the state of the vessels, structures capable of giving rise by their action to general convulsions, the "convulsive centre" of Nothnagel. On the other hand, of all regional diseases of the brain, lesions of the convolutions stand incomparably first as a cause of convulsions, and experiment also demonstrates that irritation of the cortex, in the motor region, has the same effect. The teaching of experiment, then, is that both the cortex and the medulla may originate convulsions. The teaching of pathology is, as Dr. Wilks long ago insisted, that epileptiform convulsions have, in most cases, their origin at the surface of the brain. It may be doubted, however, whether the pathological facts alone, or in conjunction with experiment, quite warrant the conclusion that epilepsy is a disease of the convolutions. Burdon-Sanderson's researches make it probable that the convulsions which occur when the surface is irritated may depend on the discharge of motor centres more deeply seated, though connected with, and excitable from, the surface regions. So far as pathology and experiment go, these deeper structures, at the level of the corpus striatum, or perhaps lower still, may be the parts which discharge in epilepsy. The fact that lesions in certain regions of the convolutions cause convulsions beginning in certain parts, as the arm or the leg, is not incompatible with this view, since discharges beginning in the lower centres may have quite the same definite forms as when they are excited from the surface. Physiological considerations make it probable that the arrangement of represented movements in the lower centres is on the same plan as in the higher. Nor does the affection of consciousness afford valid ground for the assumption that epilepsy is a disease of the cortex, since those who believe that the discharge originates in the medulla find an explanation of the loss of consciousness by assuming an extension of the discharge to the vaso-motor centre, causing arterial spasm throughout the brain. Even if we admit for a moment that there is no proof of arterial spasm, and that the over-action of motor grey matter is the only certain element in the convulsion, such over-action may disturb the centres above as well as the centres below, and, as Dr. Robertson of Glasgow has suggested, the loss of consciousness may be the effect of an upward discharge, just as the muscular spasm is the effect of the downward discharge. Thus, neither pathology nor experiment enables us to exclude the lower encephalic centres as the seat of the primary discharge in epilepsy; and in the light of all known pathological and experimental facts, the latest writer of a systematic account of the disease, Nothnagel, can see no reason to modify the conclusion that the primary seat of the discharge—the seat of the disease—is the convulsive centre in the medulla oblongata.

Pathology and experiment, then, fail to take us farther towards a definite conclusion, but from clinical observation we may gain other important information. At this point the study of the modes of onset of convulsions becomes of the highest value. The commencement in the limbs helps us but little, because, as I have said, movements in the lower centres are probably differentiated, if not as much, yet on the same plan as in the convolutions. But it is different with the auræ referred to the special senses, or consisting in mental processes. We have seen that, of all the fits which begin so deliberately as to allow the patients to be conscious of the onset, a special-sense warning is present in a fifth—that is, the discharge, as far as we can ascertain, commences in a special-sense centre. But these centres are certainly situated within the hemispheres, above the pons, and far above the "convulsive centre." Hence the conclusion seems inevitable that the discharge in such cases originates in the hemispheres. It is equally clear that an attack which begins with an intellectual aura, an idea, cannot commence with a discharge in the medulla oblongata. Such an attack we can only conceive as commencing in the highest of all the cerebral centres, that which constitutes, to use the phrase made current by Spencer and Jackson, the anatomical substratum of intellectual processes.

We may therefore conclude that the teaching of pathology, if inconclusive alone, is right in its indications, and that in at least a large number of epileptic attacks, the process of the fit commences in the cerebral hemispheres, and that in many it commences in high centres. If this is true the question arises, Are we not justified in regarding all fits as due to changes in the hemispheres? Are there any facts to indicate that the lower centres of the pons and medulla are ever the primary seat of the discharge in idiopathic epilepsy?

It is certain that convulsions may arise from these lower centres, since they may still be produced in animals after the removal of the cerebral hemispheres. Moreover, in man, convulsions are caused, in rare cases, by diseases of the pons and medulla. But the clinical facts to suggest that they ever commence in this situation in idiopathic epilepsy are, it must be confessed, scanty. Does the study of modes of onset help us in this particular? There is one group of auræ which may be regarded as supporting the view that the fits which they initiate take origin in the medulla. I refer to those which I have grouped as the pneumogastric auræ, consisting in epigastric sensations rising to the throat, choking, dyspnœa, palpitation. We know that the pneumo-

Digitized by Google

gastric nucleus and respiratory centres are in close proximity to, and connexion with, the convulsive centre, and it is readily conceivable that a commencing discharge in this situation may lead to disturbance of the respiratory and pneumogastric centres before it causes general convulsions. But on this point other facts must be taken into consideration. The phenomena of conscious sensation make it certain that the whole body is represented in the cerebral hemispheres. It is conceivable that when a discharge originates in certain parts of the hemispheres, the central structures connected with the vagus, or representing the respiratory processes, may be the seat of the first discharge, or may, at least, be the most sensitive to the commencing disturbance, and be the channel through which the consciousness is first impressed. We must remember, as we saw in the first lecture, and as Dr. Hughlings Jackson has pointed out, that these central representatives of the vagus are the most readily disturbed in emotion, such as fear. Thus the early affection of these centres, which we have just considered to be possible in a discharge originating in the medulla, is equally possible in a discharge originating higher up. Much weight cannot, therefore, be placed on the pneumogastric aura, as evidence that the discharge originates in the medulla. This conclusion is supported by cases which show that this aura is sometimes felt in attacks which certainly commence in the hemispheres. As was stated in the last lecture, this pneumogastric aura may be associated with special-sense warnings even of high elaboration, and an instance of this is the case which I related at length.

We are probably not justified in concluding that attacks never arise in the medulla. The extremely varied character of auræ, referred as they are to every part of the organism, shows that the discharge may commence in any part of a very wide region, perhaps the whole of the brain in which sensori-motor processes are represented. The cases are, however, very few which afford any clinical evidence that the discharge commences in the medulla. It is possible that, in cases of reflex convulsions, the process occurs in this situation. Almost the only example of idiopathic epilepsy which has come under my notice, in which the symptoms suggested that the discharge originated in the medulla, was a patient of my colleague, Dr. Ramskill, who kindly permits me to mention the case. A lad, fourteen years of age, had been subject to epileptic attacks for two years, when he gradually lost all power in his arms and legs, and even his neck was weak. In this condition passive movements of the trunk, slight flexion of the spine, invariably caused a severe epileptic fit, attended by loss of consciousness. Under treatment, especially ice to the neck, he steadily improved, and passive movement would no longer cause a fit, but for a long time slight attacks occurred whenever, after being still, he exerted himself. Although there was no epileptogenic zone, the attacks remind us of Brown-Séquard's epileptic guinea-pigs, in which the convulsions certainly did not originate above the pons.

The conclusion, then, is that the convulsions in idiopathic epilepsy may, as Dr. Hughlings Jackson has urged, be due to the discharge of any of the grey matter of the encephalon, which subserves sensori-motor processes. This brings us, however, to the second question, Is the seat of the primary discharge the seat of the disease? If, by such discharge, all the symptoms can be accounted for, we have no *need* to go further, and the theory that any other pathological process underlies the phenomena must rest upon its independent evidence. To learn, therefore, whether the seat of the discharge can be regarded as the seat of the disease, we must consider, first, whether there are any symptoms for which the discharge of grey matter, which causes the aura and the convulsion, cannot account; and, secondly, whether there is direct evidence of any other pathological process.

It has been supposed that the motor discharge, especially if it occur in a low centre, will not account for the loss of consciousness. We may doubt whether this assumption is justifiable with regard to any part of the brain, even to the medulla oblongata. Any small lesion of the brain, in almost any part, will cause transient loss of consciousness. All parts of the brain are intimately connected; the whole must be sensitive to a change in any one part. The maintenance of consciousness is its highest function, the first to be interfered with by any disturbance, such as results from a discharge. If the discharge originates in some cases in the lower centres, its upward effect may, as already suggested, cause a disturbance in the highest centres with which consciousness is incompatible. For the attacks characterised by loss of consciousness only, the theory held by Dr. Hughlings Jackson, that they consist in a discharge in or affecting the highest centres only, seems an adequate explanation, and is rendered probable by the fact that such attacks are often attended by sensations of a highly specialised character. In the case of the lower centres, it seems possible that a *slight* discharge in some situations may affect the centres above, and not the centres below—may impair consciousness, and not cause convulsion.

Thus it seems unnecessary, for the explanation of loss of consciousness, to assume the occurrence of any other pathological process than the discharge which causes the convulsive phenomena. As far as I am aware, the only other symptom which may be held to indicate that there is more than this discharge is the pallor of face which is sometimes conspicuous. But the peripheral vaso-motor nerves are known to be influenced, in a very ready way, by the stimulation of other nerve-structures. That pallor of face may *result* from cerebral action is proved by the effect of emotion, whatever be the mechanism by which that effect is produced. An injury to the brain of a frog will cause the arteries even of the foot to contract. Hence it is readily intelligible, and even probable, that pallor of face may be an *effect* of the discharge which causes the convulsion.

If then it is unnecessary, in order to explain all the symptoms of attacks of epilepsy, to go beyond the discharge of which we have certain evidence, we must ask what direct evidence there is of the occurrence of any other morbid process. According to current theory, another element plays an important part in producing the phenomena of attacks—vaso-motor spasm. It has been held that the discharge itself, though originating in the hemispheres, is due to vaso-motor spasm affecting particular arteries, and exciting the action by causing local cerebral anæmia. This view, which regards epilepsy as simply a disease of the vaso-motor centre in the medulla, is now held by few. It is unnecessary to discuss it separately, since the evidence on which it rests will be considered in speaking of the second view, much more widely held, that although the convulsion depends on the discharge of motor centres, the loss of consciousness is due to arterial spasm. A third theory of vaso-motor influence is that put forward by Dr Hughlings Jackson, that the local discharge in the brain excites, at the spot, arterial contraction, and that this determines the *spread* of the discharge.

What, then, is the direct evidence that vaso-motor spasm in the brain causes loss of consciousness, or any of the symptoms of the attacks? The evidence may be put, if somewhat baldly, yet I think accurately, thus:—Epileptic attacks are accompanied, at the onset, by pallor of face. Pallor—that is, anæmia—of face is evidence of anæmia of brain. Anæmia of brain will cause loss of consciousness and general convulsions. Therefore, loss of consciousness in epilepsy is due to anæmia of brain, the result of vaso-motor spasm; and, some would add, the convulsions themselves are due to the same cause.

The gaps between several of the steps of this reasoning will doubtless seem to many of you, as they do to me, considerable. But the first two statements are themselves of doubtful truth. I pointed out in the last lecture that epileptic attacks are often accompanied by no pallor of face, and this is true most conspicuously of many attacks of *petit mal*. I am convinced of this from my own observation, and I think I may quote in support of this the statement of Dr. Radcliffe, that the initial pallor is "often difficult to catch." Further, the assumption that pallor—i. e., vaso-motor spasm—of the face is necessary evidence of vaso-motor spasm in the brain seems scarcely justifiable. Surface vessels have no necessary correspondence in their condition with those of deeper structures. We do not infer that the brain is congested whenever the face blushes, and why should we assume that the brain becomes anæmic whenever the face becomes pale? We have seen that it is conceivable, and even probable, that the discharge in the brain may cause a reflex contraction of the peripheral vessels. In cases in which the pallor of face is apparently the result of cardiac failure, it is probable that this is the effect of the commencing discharge, and not its cause. Convulsion is not part of the ordinary phenomena of cardiac syncope. On the other hand, as the discharge often impresses the consciousness first through the pneumogastric centres, it is probable that it may in such cases influence the periphery first by the same channel. That such cardiac failure is not the *ordinary* cause of loss of consciousness in epilepsy a very small amount

Digitized by Google

of clinical observation will demonstrate, since such loss of consciousness may occur without either failure of the pulse or pallor of the face.

Thus between the fact that profound anæmia of the brain and medulla oblongata will cause both loss of consciousness and convulsion, and the theory that these are commonly so caused in epilepsy, there is a gulf over which no bridge has yet been placed. No connecting facts have been adduced which are not susceptible of other and better explanations. It is a gulf, moreover, which is widened by every addition to our knowledge of the clinical history of the disease.

One vaso-motor theory remains for discussion—that which assumes that a local discharge on the brain excites, at the spot, reflex vaso-motor spasm, and that this determines the spread of the discharge. This theory, I would venture to suggest, is scarcely warranted by known facts, or needed to explain them. It is unneeded, because the anatomical relations of known centres already afford us the means of explaining many facts in the progress of auræ, and justify us in the belief that the explanation of the others, still mysterious, will be found in the relations of the unknown centres, and especially, as stated in the last lecture, of those which subserve sensation. The theory seems scarcely warranted, because in all organs, as far as we know, functional activity causes reflex dilatation, not contraction, of their vessels; and the experiments of Ferrier have proved that this is as true in the brain as elsewhere.

One other point on the current theory of epilepsy may be briefly noticed—that which refers the final clonic spasm to a cause different from that which excites the initial tonic spasm. The clonic spasm is ascribed to the irritation of the medulla by the venous blood. It was, however, pointed out in the first lecture that there is no abrupt transition from the one form of spasm to the other. The clonic spasm is developed by interruptions in the tonic spasm, and as the fit ceases the muscular contractions do not become slighter, but less frequent. The clonic stage certainly corresponds to the cyanosis which results from interference with respiration, but if we recognise the continuity of the tonic and clonic spasm, we can hardly attribute the two to totally different causes. Observation of fits suggests, I think, that the venous congestion does produce the clonic spasm, not, however, by direct excitation, but by interrupting and ultimately arresting the spasm which before existed. I think that the fixation of the chest in an epileptic fit simply does in an intense manner that which we do in a slighter manner when we arrest an hysterical convulsion by closing the mouth and nose. There is nothing inconsistent in a certain degree of anoxæmia arresting spasm, and a more profound degree, as in actual asphyxia, exciting it. Analogous difference is seen in the action of many stimuli. The view that the tonic spasm is only clonic spasm compressed, that the clonic spasm is only the tonic spasm spread out, is supported by the fact that in attacks which begin slowly, the slight initial spasm is almost always clonic, and as the discharge spreads and becomes more intense, the spasm becomes tonic. In partial epileptiform seizures the spasm is usually clonic throughout.

The conclusion, then, is that all the phenomena of the fits of idiopathic epilepsy may be explained by the discharge of grey matter; that the hypothesis of vascular spasm is as unneeded as it is unproved; that there are no facts to warrant us in seeking the seat of the disease elsewhere than in the grey matter in which the discharge commences; that this is in most cases within the cerebral hemispheres, although possibly in some instances lower down in the medulla oblongata; that epilepsy is thus a disease of grey matter, and has not any uniform seat. It is a disease of tissue, not of structure.

UNIVERSITY OF OXFORD: FACULTY OF MEDICINE.—Candidates for the several examinations in medicine are informed that in conformity with the statute passed on Dec. 17th, 1879, examinations for the first (or scientific), and for the second (or practical, part) and for the certificate in State Medicine and Public Health, will be holden during Trinity Term next—i.e., at an early date subsequent to May 15th. Notice will be given in Easter Term stating the days and hours of each examination. Intending candidates are requested to forward to the Regius Professor of Medicine, "Medical Department, Museum," their names, addresses, standing, and the date of passing their final examination in Arts.

Clinical Lecture
ON A
CASE OF ULCERATIVE ENDOCARDITIS WITH EMBOLISM OF THE BRAIN.

BY HENRY THOMPSON, M.D., F.R.C.P.,
CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL.

(Concluded from p. 438.)

LET us concede that mycosis endocardii may perchance be present universally—not indeed in every instance of ulcerative endocarditis, but in every instance of the infective class as before defined. Another question remains to be asked. May we not learn a lesson from mycosis endocardii in the pathology of pyæmia? May we not see our way more clearly to the solution of the great problem, how to account for those secondary changes which, seated in front of the heart within the domain of the systemic arteries, are yet derived from sources of origin behind the heart, in the path of the venous circulation? Some instances of ulcerative endocarditis are themselves derived from this origin—in a word, they are examples of true pyæmia. In such cases there is no mystery at all. Starting from the point of invasion at the periphery, and then marching severally in single file, either alone or in company with molecules of clot, microzymes might indeed pass the barrier of the lungs; but if they were to continue on their way severally, or even in groups of a few cohering corpuscles, they would never at once block an artery or even an arteriole, whatever mischief they might do to the capillaries. On the other hand, let us suppose that the heart is their halting-place, and that here they rest for awhile and reinforce their numbers; they may then start anew, and, along with materials gathered from the heart itself, may advance in masses amply competent to stop the highway in the arteries and set up embolism there. As a rule, however, in pyæmia there is no ulcerative endocarditis, and therefore no mycosis endocardii, as the term is usually understood. Nevertheless, there may be analogous agencies at work, practically if not literally amounting to mycosis. The living organisms, and even the non-living portions of the blood-poison, when they arrive at the heart, may be free to enter into new arrangements there under new conditions. In lieu of the even onward flow of the venous circulation we have now to deal with eddying streams or stagnating pools. In these the septic elements may come into collision one with another; they may coalesce and cohere; they may react physically or chemically upon the normal constituents of the blood, so as to develop masses where before there were molecules only. With the right side of the heart we have no concern: moreover, it is easy enough without these agencies to account for the products of pyæmia in the lungs. The left heart is all-important, and here the blood is aerated, another circumstance which may have some bearing on the result. All this may appear to be wild and fanciful in detailed description, but if the secondary changes beyond the heart in pyæmia are really owing to embolism of the systemic arteries, there is much to be said for the main idea. Surely in this case the material for impaction must be elaborated in the heart, or its elaboration must begin there. If, on the other hand, the secondary changes are not owing to the cause assigned, we can only refer them in the last resort to simple thrombosis at the seat of change, or, better still, to embolism of the capillaries properly so-called. Limited to those capillaries in the beginning, the block will extend slowly backwards by overgrowth of accessory thrombi, or small superadded plugs, until the entire mass of sequestered tissue assumes the site and the proportions of a true arterial infarct. Let the pathologists of the future determine all these questions—at present they are involved in the deepest darkness.

It is otherwise, I rejoice to say, in the clinical discrimination of ulcerative endocarditis, which becomes, for the most part, clear as daylight when the teaching of a single case points the way to the diagnosis of another. You have only to do your bounden duty, and, as a matter of course, to examine the heart of every human being that comes under

Digitized by Google

your care, and it is well-nigh impossible to make a mistake. Such examination, however, is absolutely essential, for this reason. Vegetations may be growing in rank luxuriance over the valves, and yet, strange to say, there may be no præcordial distress, no local *symptom* of any sort to awaken the suspicion of mischief at the heart. Put your trust, then, in the physical signs, and, in association with the general symptoms, they will proclaim the presence of the disease with no uncertain sound. They may not, indeed, tell the whole truth at once; but wait awhile, and after one or two examinations the question will be set at rest all but indisputably. The physical signs are evermore changing from day to day in correspondence with increasing changes in the form, site, and volume of the vegetations. The systemic phenomena are severe pyrexia, and, if infection be in the ascendant, then, in full force, all the symptoms of septicæmia.

I have said that the fever of ulcerative endocarditis is often in some respects peculiar and *sui generis*. I am warranted in so saying on the assurance of two of my three last cases. In one the temperature was never noted as exceeding 102·4°, whereas the pulse ran high throughout, and in the end inordinately high. In another, that of the girl H. C——, whom you must all remember, on a few occasions the pulse marked 150; many times it ranged between 130 and 140, and never once declined below 100 from admission to death — a period amounting to three months. The thermometer, on the other hand, never showed a higher reading than 103·8°, the minimum being 97·4°, the pulse at the same time registering 138. Surely this is a strange disproportion, and one that may possibly shed some light upon the diagnosis of the disease. Both the foregoing cases were of long duration, and in both the determining cause of death was hyperæmia and œdema of the lungs, exactly as might have happened at any moment to anyone suffering from heart disease without the aid of a blood-poison to accelerate the issue. The case of M. T—— differed widely from its predecessors. She died within a fortnight, and in her the blood-poison reached a high pitch of intensity. Moreover, in her there was no disproportion of the kind above-mentioned, or, if it existed at all, the ratio was reversed, and the temperature transcended the pulse-rate. Perhaps the hyperpyrexia, which closed the scene, may be reasonably referred to acute brain-softening, with meningitis, the consequence of that softening, and not to simple septicæmia. Be that as it may, it is the hyperpyrexia characteristic of severe shock or injury to the nervous system at its climax, and finds its nearest and best parallel in cerebral rheumatism, and occasionally in tetanus and lesions of the spinal cord. In M. T——, however, the temperature, though fitful and oscillating as in pyæmia, still maintained a high general average all along, and often reached or passed the uttermost limits of pyrexia proper, even before the occurrence of embolism in the Sylvian artery. Are we, then, at liberty to say that in the milder forms of ulcerative endocarditis the pulse-rate is ruled by the bulk and burden of the vegetations, provoking the heart to excessive action, but not materially exalting the fever-heat; while in cases that are truly and thoroughly infective the blood-poison is the overruling power that governs the course of events, and gives full expression to the fever in all its phases?

Other symptoms there are or there may be to which I should accord a high value and a strong significance. First, let me mention a marked apathy in the patient, an utter indifference to everything and everybody around him, sometimes alternating with delirium. Whenever I have found a murmur or a medley of murmurs at the præcordia, I have learnt to look upon delirium in the light of a symptom suggesting embolism of the extreme arterioles of the brain, chiefly in the cortical system of the convexity. M. T—— exhibited unconcern and indifference enough, apparently owing to sheer helplessness and abolition of all mental power. Usually I have seen it in the guise of reverie and dreamy abstraction. Such demeanour was not to be expected in M. T——. In her the Sylvian artery was plugged at the main, there was extensive softening of the central ganglia and their environs, and there was meningitis. In the girl H. C—— dreaminess was a conspicuous feature, and in her brain we found a minute focus of yellow softening near one of the parietal convolutions.

Another special symptom, and a most inauspicious one when it occurs, is an eruption of spots resembling petechiæ, and evidently originating in capillary embolism. As for embolism on the large scale, endangering life or limb, even when its presence is fully ascertained, I exclude it from the reckoning altogether, and for a good reason. I wish you to understand the case with all possible speed before such embolism arrives, and not to await its arrival.

Last, but not least, in the catalogue of special symptoms is profuse drenching perspiration, second only, if it be second, to that of ague, and far beyond the average mark and measure of phthisis or abscess. In all my recent cases of ulcerative endocarditis I have invariably met with this superabundant sweating, so that, in my mind, it is now fairly enrolled among the leading indicia that would guide me on the way to a right diagnosis. I dare not, indeed, affirm that sweating is universally present. In an old and ill-recorded case of my own there is no mention made of it in the notes.

Finally, I have to comment upon the insensibility of the entire left side, associated with left hemiplegia, as a result of the embolus in the opposite side of the brain. Hemianæsthesia, intense in degree and bounded with geometrical precision by the median line of the body, is far from uncommon as a symptom of hysteria, if we may accept the averments of the French authorities. Briquet and Charcot assure us that hemianæsthesia, perfect in all its points, occurs in 93 out of every 100 cases—that is to say, in upwards of 23 per cent. of all hysterical women. I can hardly imagine it to be so common in England; indeed, I am sure it is not; but then we are far behind the French in all the mysteries and marvels of hysteria. In the vast majority of instances you will be at no loss to discern the underlying neurosis, which will ordinarily be certain to betray itself by one or more of its familiar features, although you would do well to remember that M. Charcot has met with mixed cases truly cerebral and truly hysterical at once. Nay more, he has encountered a few cases of purely cerebral origin presenting all or nearly all the characters of hysterical anæsthesia. With reference to the pathology of the cerebral form, M. Charcot, after long wavering between many regions whose morbid changes might possibly determine hemianæsthesia, comes at last to the conclusion that the posterior part of the internal capsule is alone responsible for the result. At any rate, it is the only part which is found to be invariably destroyed or damaged in all cases of predominant and persistent hemianæsthesia where the lesions are circumscribed. Now, the internal capsule lies wholly within the domain of the Sylvian artery, a domain in the present case utterly disorganised by interception of its blood-supply at the fountain head—hence the hemianæsthesia. The hemiplegia needs no commentary. Cases of this kind are not numerous. The reason appears to be that the plug is usually seated at the point of a bifurcation, and not at the origin of the vessel. It is interesting to note how closely the lesions follow the lines of anatomy. The softened structures are all comprised rigorously within the range of the Sylvian artery; the unsoftened portions of the great central ganglia lie more or less beyond that range; their blood comes wholly or partially from other sources—in the corpus striatum from the anterior cerebral artery, in the optic thalamus from the posterior cerebral.

Regional diagnosis of brain disease offers many beautiful problems for solution. Has it any corresponding advantages in practice? It is a sad tale to tell, but I am afraid these advantages have been immensely overrated. For all that, I should be the last person to disparage or discourage it in its proper place, chiefly as a matter of medical science. On general principles, I should say in medicine, as in everything else, let us by all means solve all the problems we can. We never know what fruit our investigations may bear in time to come, however barren and unpromising they may seem to be now. Again, in a few particular instances, localisation may enable us to forecast the future of a case. If, for example, there are grounds for ascribing the symptoms to the medulla or its environment, then beyond a doubt life is most seriously compromised. Darker still are the prospects of recovery when we have reason to believe that an extravasation of blood has forced its way freely into the ventricles of the brain. Finally, if we ever meet with another case of hemiplegia and hemianæsthesia conjoined, and know that it is the result of embolism, the chances are that the embolus must be lodged *in limine* at the very commencement of the Sylvian artery, over and against the points where the basal branches are given off from the main trunk. I need not tell you that a lesion so situated would be imminently perilous to life. I am not aware that there exists in the arterial system around the spot any mechanism competent to save,

Digitized by Google

from utter destruction the ganglionic territory within the sphere of the Sylvian artery, however it may fare with the convolutions and the cortex. Not that I should refer the rapidity of the softening process to this cause alone. Large allowance must be made for collateral agencies, for the fever of septicæmia, and for the general depravity of the blood and tissues. Even in our case the constitutional symptoms and the nature of the lesion must be taken into account. The mere site of the mischief in a particular region of the brain is only one item in the reckoning, and in the majority of cases it is only a subordinate item. Lastly, let me ask, will regional diagnosis avail you much in the matter of treatment? I fear not. It availed me nothing, or next to nothing, in my own case. It was there addressed chiefly to the pyrexia and the prostration. What in the world could I do with the embolus? As for the meningitis, I knew nothing of it before death, and, if I had known of its existence during life, no measure of mine would have made the slightest impression upon it.

ON THE TREATMENT OF CANCER OF THE FEMALE GENERATIVE ORGANS BY A NEW METHOD.

By PROFESSOR JOHN CLAY,
OBSTETRIC SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

In the following observations I intend to confine myself to the consideration of the treatment of carcinomatous affections of the generative organs, by a new method which I believe to possess great advantages, though as the experience of this particular treatment extends over a period of only twelve months, sufficient time perhaps has not elapsed, in some of the cases, to enable me to state positively that a permanent cure has been effected. It will be obvious, however, on reading the clinical facts here submitted, that if this ultimatum has not been attained, an amount of relief has been secured to the patients which has not been afforded by any other plan of treatment.

The researches of modern pathologists have done much to elucidate the nature of cancer, and have at least reduced to their anatomical elements changes of structure so singular and complicated that they seemed at one time to defy description. To define the histology and morbid anatomy of cancer does not come within the scope of this communication. There are certain facts of cancer which are obvious and indisputable—namely, that it is a definite morbid growth, possessing, among other qualities, rapidity of development, never retrogressive, but having an almost certain tendency to invade, step by step, each surrounding texture, without any distinction, extremely prone to recur on removal by operation or caustic agencies; very liable to attack distant organs, and invariably culminating in a fatal issue. This general description applies notably to cancer of the female generative organs, perhaps the most painful and frequent of all the forms of this disease which affect the human system. The patient's sufferings are aggravated by the knowledge that her disorder is pronounced by the medical adviser to be incurable; she lingers under the double torment of excruciating physical agony and mental depression, and the utmost that can be done by the medical attendant is to afford her the tenderest sympathy while deadening the anguish of the patient by the judicious use of sedative remedies. Divergence of opinion has existed as regards the curability of true cancer, probably ever since medicine has been studied as a science. On the one hand, those who deem cancer to be incurable urge that the infecting character of the disease, its multiple manifestations, its recurrence, and the cachexia which it induces afford incontestable proof of its incurable nature. The advocates of the theory of the curability of the disease deny the absolute fact of primary cancerous infection, and in support of their view quote cases which, after treatment, have not suffered relapse. Opinion, while deserving serious examination, does not carry conviction, but facts plainly and truthfully narrated, and corroborated by independent testimony, will always be received by the profession without prejudiced scepticism, and with an earnest determination to test their validity. Impressed with these views, fortified with a consciousness of the importance of the clinical investigation which I have made during a long period as to the curability of cancer, I venture to submit to the profession my most recent experiments, in the hope that suffering humanity may at least be benefited by their publication.

As the result of an extended trial of a large number of remedies, both general and local, in the endeavour to cure cancer, the conviction forced itself upon my mind that a remedy for this disease must be one to be administered internally, and that it must be of such a nature as not to interfere with the functions of the special organs, or otherwise to injuriously affect the nutrition of the body, and that it must also be capable of being administered for a length of time sufficient to effect the removal of the disorder. A large number of remedies for the cure of cancer mentioned by various ancient and modern authorities, as well as some hitherto untried, which suggested themselves to me, were employed empirically, but they failed to produce an appreciable effect in curing or arresting the disease. At length, after a careful study of the pathology of cancer, and the effects of certain carbo-hydrates administered internally, it appeared probable that a remedy for cancer might be found amongst them. A list of those apparently most eligible was made, but, after studying their therapeutic properties, it became obvious that most of them were unsuitable for the purpose as possessing commonly known specific properties, as well as exciting a special action on certain structures and organs of the body. Besides, their administration could not be expected to be sustained for a sufficient length of time, even if they were likely to act on the morbid growth. Circumstances, however, led me to think differently of the Chian turpentine, and I determined to try it on the first opportunity. This soon occurred. A woman came to the hospital as an out-patient, aged fifty-two. She was suffering from scirrhous cancer of the cervix and body of the uterus. Hæmorrhage was excessive, pain of the back and abdomen agonising, and cancerous cachexia well marked. The patient evidently had not a long time to live. The uterus was so extensively destroyed by the cancerous ulceration that its cavity readily admitted three fingers. In such a case it appeared to be justifiable to attempt to relieve the sufferings of the patient, even if the remedy should produce unfavourable symptoms, or should prove of no avail. I therefore prescribed Chian turpentine, six grains; flowers of sulphur, four grains; to be made into two pills, to be taken every four hours. *No opiates were prescribed* or lotion used. No change was to be made in her diet or occupation. On the fourth day after taking the medicine the patient reported herself greatly relieved from pain, and was in better spirits, but she complained of a large amount of discharge. It was feared that she referred to a discharge of a sanguineous nature. On examination, however, the vagina was found to be filled with a dirty-white secretion, so tenacious as to be capable of being pulled out rope-like, and this although she had syringed herself three hours previously. The os was quite contracted and would now scarcely admit the finger, and the surrounding swelling or cancerous infiltration of the cervix was much reduced. On the twelfth day the thick tenacious secretion had almost disappeared, and was succeeded by a somewhat copious serous fluid. The os was not so firmly contracted, but would only admit the finger. The patient's general health was improved and the medicine well tolerated. Sixth week: I ordered her a quinine mixture, in conjunction with the turpentine, but sickness supervened, which ceased on omitting the quinine. Twelfth week: My notes are—the parts feel ragged and uneven, and do not bleed on roughly touching them. The speculum shows several cicatricial spots. The turpentine has been taken regularly during the day for twelve weeks every four hours, during which time she has been almost free from pain and has had no hæmorrhage; no glandular enlargement; general health improved. Walks easily to the hospital, being about a mile distant. As the patient did not come again to the hospital her address was obtained, and it was ascertained that she had left her residence. Being a widow she could not afford to keep her home, and she went to reside with her married daughter in a northern town; but left no address. The case showed that the medicine was one of great power in cancer of the uterus, and it is to be regretted that an opportunity was not offered for fully carrying out the treatment.

Another patient, aged thirty-one, suffering from cancer of

Digitized by Google

the os and cervix uteri, was treated concurrently with the one just mentioned. These parts were enlarged from carcinoma to the size of a hen's egg. The os was dilated, and the cavity of the cervix was filled with epithelial growths, which bled freely on examination. Sacral pain was very severe, and hæmorrhage had been continuous for the previous six weeks. The Chian turpentine and sulphur were given as in the previous case. The patient again attended at the hospital on the seventh day after taking the medicine. She was in excellent spirits, and expressed her gratitude for the relief afforded her. The medicine entirely relieved her pain. She had increased white discharge. On examination the os and cervix were found to be nearly of the normal size. The os was patulous, and its surface was studded with flabby shot-like eminences, which did not bleed on roughly rubbing them. I said to her, "You are better; you must continue the medicine." She answered, "I should think I must, for I could not do without the pills; they have eased me so very much." She continued to improve, and on the fourth week she expressed herself as quite well. I impressed upon her the necessity of continuing the medicine, and told her to see me occasionally. She did not come to the hospital again for four months, when she brought another patient to consult me, believing that she was suffering from cancer. I reproved her for leaving off attendance at the hospital. She answered that she thought it unnecessary, as she had continued quite well. On this visit she submitted to an examination. The os was rough and irregular, but was of nearly the normal size; no signs of cancerous infiltration; the periods were regular, and not profuse, and were unattended with pain; there was slight leucorrhœa. This case was a most remarkable one. The turpentine acted upon the growth with great vigour, literally melting it away in the brief period of four or five weeks.

The third case was one of epithelial cancer of the os, cervix, and body of the uterus, in a woman, aged fifty-two years. The vagina was not involved. The mass was larger than a cricket-ball, almost filling the vagina. The border of the os was three-quarters of an inch in thickness, forming a ring of two and a half inches in diameter, through which protruded an epithelial growth, principally proceeding from the anterior wall of the uterus, and projecting about two and a half inches into the vagina. The case was sent to the hospital for my opinion by my son, Mr. Langsford Clay, who had attended the patient but a short time. The journey to the hospital fatigued her very much, and she declared that she could not come again, and that she did not wish to remain as an in-patient, believing that she could not live many days. She had repeated hæmorrhages, had much pain, and had the cancerous cachexia well pronounced. My son volunteered to attend her at home, and I agreed to see her occasionally with him. I thought it advisable as an experiment to vary the treatment somewhat, and ordered to be added to the pills one-sixth of a grain of the ammoniated copper, as from the large mass to be acted upon I thought that an astringent should be superadded to the turpentine. The dirty-white tenacious discharge appeared and continued for the first five weeks, but there was no hæmorrhage after the first examination. The swollen os uteri and the cervix beyond were the first to show signs of diminution; this was noted on the fourteenth day. The tumour, however, was rough and shrunken, and did not project so much. Sixth week: The surface of the tumour was at the level of the os uteri, and seemed to consist of a mass of bloodvessels which bled moderately after examination. This condition occasioned me some surprise, as three weeks previously the patient was ordered a lotion made with perchloride of iron, with a view to arrest hæmorrhage, since from her anæmic condition it was feared that the loss of a moderate amount of blood would be followed by serious consequences. I asked her what kind of syringe she used with the lotion. She replied, "I thought the lotion was merely to bathe the external parts." This, as it happened, was very satisfactory information, as it showed that the lotion had no share in the reduction of the mass, which now was scarcely half the original size. She was supplied with a syringe for the purpose of applying the lotion, and after using it three days the mass of vessels had considerably shrunken, and no longer bled on manipulation; but the surface of the growth had the touch and appearance of a gangrenous mass, but there was scarcely any fetor. The patient now complained of gastrodynia, with colicky pains in the bowels, but she had no diarrhœa or vomiting. I believed this to be due to the copper, and it was consequently discontinued. It also occurred to me that the turpentine might not be efficiently digested in the solid form, and that it would be better if the remedy were administered in a state of minute subdivision, as in the form of an emulsion. An ethereal solution of Chian turpentine was prepared by dissolving one ounce of the turpentine in two ounces of pure sulphuric ether (anæsthetic). The ether dissolved the turpentine instantly. This solution was given to our skilful dispenser, Mr. Whinfield, with a request that he would prepare a pleasant mixture or emulsion from it, and after a few trials he prepared one which is not unpleasant to take, according to the following formula:—Solution of Chian turpentine, half an ounce; solution of tragacanth, four ounces; syrup, one ounce; flowers of sulphur, forty grains; water to sixteen ounces: one ounce three times daily. This form of mixture was given to the patient, and was much liked. She has now taken the turpentine for thirteen weeks uninterruptedly. The os uteri is a little more than one inch in diameter, and feels like a ring of cartilage about a quarter of an inch in thickness. The tumour has nearly disappeared, and the finger can be introduced posteriorly into the uterus for more than an inch. The general health has much improved, and she is quite free from pain and looks cheerful, and is becoming stouter. No sedative whatever has been given during the treatment. Fourteenth week: She complained of severe "cramp-like pains" in the back and lower part of the abdomen, which she attributed to the mixture, and in consequence it was discontinued for a few days, and an opiate given, by which she was greatly relieved. The turpentine was again resumed. Nineteenth week: She is now fairly convalescent. The growth has almost disappeared, and the parts beyond the os uteri are somewhat hypertrophied, yet are almost normal to the touch.

The fourth case was that of a patient aged thirty-two years, who came to the hospital after having been discharged as incurable from the Women's Hospital. She was greatly depressed, and was most desirous to be cured, for the sake of her family of young children. She has had repeated floodings, and suffered greatly from pain during the past five months. Constipation very troublesome, which probably arose from the opiates she had been in the habit of taking. On examination, she was found to be suffering from epithelial cancer of the os and cervix uteri, but not involving the vagina. There was a cancerous mass of the posterior parts of the os and cervix, of the size of a goose-egg. This growth pushed the os uteri towards the pubis, almost preventing that part from being felt. The turpentine mixture was given her three times daily, and from this period a very rapid diminution of the growth took place, so that by the sixteenth day it had almost entirely disappeared. The os uteri was now *in situ*, admitting the finger readily, and there was the same condition of the vessels as that observed in the preceding case. The lotion with the perchloride of iron was used daily for a few days with excellent effect. In the ninth week the patient suffered from spasmodic pains in the back and abdomen, and as this was attributed to the medicine it was discontinued, and iodide of calcium, in five-grain doses, three times daily, was administered. This was taken for about a fortnight, but, not feeling so well, the patient was admitted into the hospital. The condition of the internal organs was now much the same as before, the iodide of calcium was given, but there was some thickening about the cervix, which was fixed to the vagina. The rectum was excessively loaded, and required several days to effectually relieve it. The Chian turpentine was administered simply; but a lotion was prescribed, containing six grains of white arsenic to one pint of water, to be used daily. Under this treatment the woman very rapidly improved, the pains entirely ceased, and the parts became much reduced in size and more movable. The patient was now anxious to leave the hospital for her home, as she felt quite well; but it was deemed advisable to send her to the Sanatorium instead. She is very active, cheerful, and happy, and may be pronounced convalescent.

Other cases are under treatment, both in the hospital and privately, all showing similar effects. The remedy is now being tried in cancer of other organs, and apparently with good results. One of the most interesting, perhaps, is a case of scirrhus of the breast, which has been under observation for some weeks. Among the other cases are cancer of the vulva, stomach, and abdomen, in which very remarkable benefit has been already produced.

From the results obtained by the use of Chian turpentine,

Digitized by Google

it may be confidently said that the remedy does exert a powerful action on cancer of the female generative organs in particular, and it will be of advantage to point out some of the conclusions at which I have arrived respecting the efficacy of the drug and the manner in which it should be employed. The oil of turpentine, if it produces any effect on cancer, is inadmissible on account of the speedy production of its specific effects even when administered in small doses. The same remark applies with less force to the Venice and Strasbourg turpentines; in my hands they have not produced the same beneficial effects on cancerous growths as the Chian turpentine has done. The maximum dose of the last-named drug which can be safely and continuously given is twenty-five grains daily. It is advisable to discontinue the remedy for a few days after ten or twelve weeks' constant administration, and then to resume it as before. The combination with sulphur was given at first, and has been continued. It is doubtful whether much benefit is derived from the combination, but the effects have been so uniformly good with it, that it was thought advisable to continue its use. There is every reason to believe, from the trials made with other substances in combination with the turpentine, such as carbonate of lime, iodide of calcium, ammoniated copper, quinine, bebeerine, hydrastin, &c., that the turpentine is best administered simply, as the most marked and rapid effects have always been manifested when it has been given alone.

The turpentine appears to act upon the periphery of the growth with great vigour, causing the speedy disappearance of what is usually termed the cancerous infiltration, and thereby arresting the further development of the tumour. It produces equally efficient results on the whole mass, seemingly destroying its vitality, but more slowly. It appears to dissolve all the cancer cells, leaving the vessels to become subsequently atrophied, and the firmer structures to gradually gain a comparatively normal condition.

It is a most efficient anodyne, causing an entire cessation of pain in a few days, and far more effectually than any sedative that I have ever given. In the cases I have described no sedative was employed in any instance, although in some cases where great pain had existed previously to commencing the treatment, large doses had been given. Whether this arrest of pain arises from the death of the tumour, or, as my son suggests, is due to there being no longer irritation of the sentient nerves (in consequence of tension being withdrawn by the removal of the cells), the fact is the same.

If, after the use of the remedy for some weeks, one of these cases were examined by a stranger for the first time, he would probably conclude that it was one of commencing malignant disease, by reason of the irregularities of its surface. The effect of the remedy being first to remove the cellular structures, any loss of tissue produced by the invasion of the disease cannot be restored, and hence the irregular touch and appearance even after cicatrisation. The arrest of the hæmorrhagic discharge and the remarkable freedom from glandular affections, after a lengthened use of the turpentine, are specially important factors in materially aiding the removal of the cachexia and of improving the general condition of the patient.

Without being in a position to affirm that the Chian turpentine is a positive cure for advanced cancer of the female generative organs, yet however the facts here adduced may be interpreted in this respect, two circumstances are indisputable—one, that all the patients after several months' treatment are living, and that the disease has not advanced as is usually the case, but has retrogressed—in fact, has all but disappeared; and it may at least be safely asserted that when the remedy is steadily used for some time it arrests the progress of the disease, and relieves the pain incidental to the morbid growth in a manner which cannot be said of any other remedy. It is probable that on an extended experience of its use and by variations of the mode of administration, it may prove an effectual cure for this intractable disorder. Patience and perseverance on the part of patient and medical adviser are absolutely required. We know that in some diseases, as bronchocele and syphilis, a long continuance of well-known remedies is often necessary to effect a cure of the particular disorder, and that the administration of the remedies has to be varied from time to time, according to the therapeutic effects produced by the drugs. In cancer, as far as experience has at present indicated, the same alternating method may perhaps have to be employed. Whatever may be the ultimate results there can be no doubt that Chian turpentine in these disorders is a most valuable medicine. Judging by my experience it is no figurative expression to say that it acts as a direct poison upon the growth, probably causing its ultimate death. In advanced cancer the process of reparation is slow, but if the surrounding structures are not too much involved in the process of destruction, it will seem that a cure may be reasonably expected. It is not that the remedy has failed against the cancer, but that the vital organs are so much destroyed that their complete reconstruction and adjustment of functions are not possible, and life fails in consequence of their mutilated condition. Even under these circumstances, if the cancer does not recur, the efficacy of the medicine is obvious. In the early stages of cancer it may be affirmed that an undoubted cure may take place speedily, and as the contiguous structures are not extensively involved, but little deformity ensues; and experience justifies the expectation that under such circumstances a recurrence of the disease will not follow.

The history of the local treatment of cancer of the uterus is one of singular interest, and is highly instructive to the practical physician. The contrast between the general and local treatment is the more notable, as nothing can be more injurious to the welfare of the patient than an attempt to destroy the cancer by external agencies. The disease is not to be averted by this means, as the symptoms assume a more intense and threatening character, until the patient rapidly sinks. It may be observed that the internal treatment here recommended when used for a considerable period is borne by the patient with remarkable tolerance. As I have mentioned, in some of my experiments I determined, in order most thoroughly to test the medicine, to rely upon this alone. Recently the arsenical lotion has been superadded, and, with no injurious consequences—it appears to act as a disinfectant, and it may produce some benefit by promoting the cicatrisation of the tissues. Several suggestions offer themselves for inquiry as to aiding locally the detachment of the growth, after its vitality has been destroyed; but this is not of much importance, as there seems to be no fear of the blood becoming affected by the absorption of the decaying tissues, the turpentine probably preventing any such calamitous occurrence.

If the practice now described should prove by future experience to be justified, then it will be incumbent upon the medical adviser to treat cancer of the generative organs at an early stage of its development, and it is reasonable to conclude that this dreaded and most fatal disease will no longer be the scourge it has hitherto proved, and that another benefit will have been conferred upon suffering humanity by the resources of therapeutic art.

Birmingham.

ON

ANÆMIA AS A CAUSE OF HEART DISEASE.[1]

BY JAMES F. GOODHART, M.D.,

ASSISTANT-PHYSICIAN TO GUY'S HOSPITAL AND THE EVELINA HOSPITAL FOR CHILDREN, DEMONSTRATOR OF MORBID ANATOMY AT GUY'S HOSPITAL.

I SHALL base the remarks that I have to make upon this subject on the following four cases:—

CASE 1. *Hæmorrhage from the Uterus after Miscarriage; Fatty Heart.*—Emma S——, aged twenty-three, was admitted to Guy's under my care on April 26th, 1878. She had always been strong and healthy till her present illness. Three months before her admission she had a miscarriage, and lost a large quantity of blood, and ever since that time she had, at intervals of five or six days, been subject to repeated hæmorrhage, the last on April 20th. She was much wasted and completely blanched. The blood contained some 200 white corpuscles in every field, and the red corpuscles were much diminished in quantity. The viscera were normal except the heart, the action of which was very violent, and the beat diffused and cantering. There was a rough double sound at the base, with a systolic bruit to the left of the sternum. She died very soon after her admission, and at the inspection the heart was found thus:—The peri-

[1] Read before the Harveian Society, January 15th, 1880.

Digitized by Google

cardium contained two ounces of clear serum. There was no pericarditis. The heart weighed eleven ounces. The left ventricle was a little dilated. Tabby striation was well marked in the musculi papillares, and in some parts of the wall of the left ventricle and also beneath the pericardium, particularly in the right ventricle. The valves were all healthy. The ventricles contained some poor, half-coloured clot. There was no appearance of leucocythæmia. The spleen weighed six ounces, the liver forty-three ounces, the kidneys nine ounces; all were quite bloodless, but not otherwise diseased. The cause of the hæmorrhage was found to be a slough of somewhat obscure origin in the uterine wall.

CASE 2. *Sarcoma of the Bladder; Hæmorrhage; Anæmia; Tabby Striation of the Heart with Dilatation.*—A man, aged thirty-four, was admitted under the care of Dr. Habershon, who has kindly allowed me to quote the case, for hæmorrhage from the bladder. This was first noticed when he was a boy, and the bleeding had returned many times at intervals, but latterly with severity and the passage of coagula. He died a month after his admission, and during the last few days of his life his temperature was pyrexial. The heart weighed sixteen ounces. There was a well-marked tabby change in both ventricles, the striation being well marked beneath the endocardium, and the left ventricle was dilated. The coronary arteries were good, and there was no excess of fat externally. The cause of the hæmorrhage was a large cauliflower growth of medullary sarcoma at the base of the bladder. The viscera were pale and bloodless, but not otherwise diseased.

CASE 3. A woman, aged forty-five, had suffered from severe hæmorrhage from a uterine fibroid. The hæmorrhage was so severe, that one of her legs became gangrenous, and she was admitted for this under Mr. Cooper Forster's care. She was extremely blanched, and for some time nothing could be done, but at length the limb was amputated, and she improved. After a time, however, she had rigors; a large bedsore formed, and uncontrollable diarrhœa carried her off. She was much emaciated. Chronic abscesses were found in her lungs and kidneys; thrombosis of the vena cava and other large veins beyond it; and the muscular tissue of the heart was in a state of tabby striation. The heart only weighed seven ounces.

CASE 4 has been already recorded at the Pathological Society, but shortly it is this. A boy, aged six, was admitted on October 8th, 1869, under Dr. Pavy. He had been taken ill seventeen days before admission, and his symptoms were those of well-marked typhoid fever, the pyrexia running as high as 105° on the twenty-seventh and thirty-first day of his illness. A rather copious hæmorrhage from the bowel occurred on the twenty-ninth day of the fever, and a second more profuse on the thirty-first, associated this time with epistaxis. This left him very blanched and exhausted, and he died four days later quite suddenly. At the inspection the muscular tissue of the heart was very pale, and the sub-endocardial muscle was markedly tabby from degeneration; the left ventricle was considerably dilated, and to this I think his sudden death may have been due. All the viscera were very bloodless and the lungs œdematous. The hæmorrhage from the intestine had come from a deep, almost perforating, ulcer in the mucous membrane of the descending colon, which with several others of like nature was situated on the mesenteric attachment.

In all these four cases there was a well-marked change in the muscular fibre of the heart. I have called it tabby striation rather than fatty degeneration, because all of us will admit that there is a degeneration of some sort—and therefore disease; perhaps all would not be willing to admit that its nature is fatty. I myself should allow that the change is one which does not yield very definite microscopical results. The muscular tissue alters and becomes granular, takes staining fluids badly and loses its striation—whether it is actually fatty may be a matter of question, though the change is one which is termed fatty degeneration by, I believe, all pathologists. It is not my purpose here, and I wish to treat the subject in its most practical bearings, to discuss the mode of production of the morbid material. I bring the cases forward as an anatomical basis for the assertion that simple bloodlessness, with of course the changes which are its consequents in the composition of the blood, is a cause of heart-disease, without entering into the question how the disease is produced. To the first three of them I do not think any objection can be taken, but to the fourth it may be said that the continued fevers are in themselves sources of muscular degeneration, and that the case being one of typhoid fever is a sufficient explanation without calling the hæmorrhage into account. This view is possibly correct, though the change described is but a very occasional accompaniment of typhoid fever. It may also be objected that the change occurred too rapidly, the hæmorrhage commencing but a few days before the child's death. To that I would reply that phosphorus-poisoning leads to changes of like nature in the muscles quite as rapidly as I suppose the anæmia to have done.

It is no new idea that anæmia leads to mal-nutrition of the heart. Walshe writes, "In cases where anæmia has either been persistently or with occasional intermissions sustained for a more or less lengthened period, it is probable that changes are effected in the structure and properties of the tissues of the heart;" and with special reference to the occurrence of fatty degeneration he writes, "Cardiac anæmia has frequently fallen under my notice as the immediate prelude to fatty metamorphosis." Ormerod, in his "Clinical Researches on Fatty Degeneration of the Heart," observed three cases similar to those I have given; Virchow has noted its existence in chlorosis, and Ponfick has described a form of fatty degeneration as the result of chronic anæmia and hydræmia.

The disease, too, called idiopathic anæmia is constantly, and is well known to be, associated with a similar change in the muscular tissue of the heart; though upon this class of cases the hæmorrhagic group have an important bearing, because we know nothing about idiopathic anæmia except what its name reveals to us, and there is always a suspicion behind it that simple bloodlessness may not be its essential element, and that the fatty heart may be part of that other something of which as yet we are in ignorance. Fatty heart ensuing upon recurrent hæmorrhage shows that the simple bloodlessness can and does produce a state of heart precisely similar to that found in idiopathic anæmia, and the two series of cases thus tend to corroborate and enlighten each other.

With the body of evidence thus obtained we may next associate certain ascertained clinical facts. The chlorotic heart is sufficiently well known hardly to need mention, but I may just say that in it, and not in it only, but in all forms of anæmia in women, the heart's impulse becomes diffused and displaced outwards; the first sound is sudden and excited, and associated with these are the subjective symptoms of breathlessness and palpitation. This subject has received attention in a very careful and suggestive paper by Dr. Pearson Irwine[2] in this country, and by several writers abroad.

There are many explanations of these various phenomena, but I can only say now that the best, or at any rate the safest, appears to me to be that derived from post-mortem evidence, and which demonstrates that anæmia is associated with degeneration of the heart muscle, and which therefore points directly to dilatation of the left ventricle as the cause of the symptoms. The heart in such cases is from all we know of the morbid anatomy of anæmia, actually in a state of fatty degeneration; it has become dilated, and hence the symptoms complained of. The same remarks hold good with regard to children, in whom there is no affection more common or brought about by a greater variety of circumstances than a persistent anæmia. For the past few years I have been in the habit of making observations on my out-patients at Guy's Hospital and the Evelina Hospital on the position and the sounds of the heart in these cases, with reference to the beginnings of heart disease, and as in women, so in them, the heart's impulse is generally widely diffused, often to an inch external to the nipple; the rhythm is irregular, while the sounds are for the most part considerably altered, the first sound being prolonged, confused, or thick, if there be not actually a systolic murmur. I believe with Parrot, Balfour, and others that temporary dilatation occurs in these cases, and leads to some incompetence of the mitral valve so long as it persists, and to this is due the systolic apex-bruit that is so frequently present. I am aware that some authors, of whom I may mention Fagge and Pearson Irvine, are of opinion that the bruit in many of these cases is due to eddying currents behind the mitral valve in a dilated ventricle, and I see no reason to object to this view as an alternative one. But if we accept the dilated state of the ventricle as a fact in anæmia, we may

[2] The paper in question was read at a meeting of the Royal Medical and Chirurgical Society, but has unfortunately never been published except in abstract in the Proceedings.

Digitized by Google

take it as granted from what we know of the conditions under which the mitral valve acts that there must also be regurgitation in a good proportion of cases.

So far I think the facts are clearly in favour of all that I have attempted to draw from them, and the subject even hitherto is one of such moment to so large a number of persons, that I would have the teaching in our text books much more decided than it is. Prolonged anæmia leads to fatty degeneration of the heart at all ages, and during the existence of such anæmia, it is therefore imperatively necessary that the heart be rested as much as possible, and the anæmia should be dispelled with all possible celerity.

But this is not my main point. I should rightly be told that there is nothing new in this. There is not; but it is a step necessary to develop my main contention which follows—viz., that anæmia, by leading to dilatation of the left ventricle, is a fertile source of valvular and chiefly of mitral disease. If what I have said be true, it follows that this is highly probable. Anæmia leads to fatty changes in the heart. Fatty changes in the heart favour dilatation of the left ventricle. Dilatation of the left ventricle disarranges the coaptation of the mitral flaps, and mitral regurgitation results, the so-called curable regurgitation. But if this regurgitation is prolonged for any length of time, or is frequently repeated, as is not unusually the case in many instances of chlorosis, surely from the passage of blood in two directions instead of one, and particularly when the backward stream is such a twisted and rough stream, if I may use such a term of fluid, as is the regurgitant mitral stream, there must be a considerable increase of friction or wear and tear to the valve, and chronic disease of the tissue of the valve is started, which by and by—it may be years after the original cause has ceased—leads to permanent thickening and disease of the valve. This train of events, I say, has much of probability in its favour; yet where is there actual evidence of the existence of the evil? I appeal in vain to the standard authorities. Nevertheless I think it is to be found. It is not possible to prove the point to demonstration, as I have the dependence of muscular changes upon the anæmia, but its probability may be shown by an appeal to some facts which seem to me to be of considerable significance. First of all, I would mention that when there has been prolonged regurgitation on the right side, the tricuspid is generally considerably thickened. It is true that, under such circumstances, it never, so far as I know, approaches to any condition that could be called stenosis; but this deficiency in the parallel between the two valves is, I think, sufficiently accounted for by certain mechanical differences between the two sides, and by the difference in the amount of work performed by each. Secondly, I would say that but seldom in cases which are due to a primary muscular fault and to consequent failure of the mitral valve by stretching, do we find the mitral condition one of simple dilatation; the dilatation is very commonly associated with more or less thickening of the chordæ tendineæ and the edges of the valves. Here, again, we find no stenosis; but contraction takes time, and this class of cases is in the main composed of senile muscular failures and degenerations, which are rapid in their course. Take, next, another fact, less well known than it ought to be—viz., that in a large number of cases of chronic renal disease there is a notable and sometimes extreme thickening of the mitral flaps.

The facts bearing upon this that I have collected are these. In 192 consecutive cases of chronic renal disease of various kinds tabulated from our post-mortem records, 72, or more than a third, had some thickening of either the mitral or aortic valves, or of both. In 49 of these the mitral was either thickened or actually contracted. The mitral was contracted, and therefore very thick in nine cases, and all nine, without exception, were cases of small, contracted, or granular kidney. Ninety-seven of the 192 cases were examples of granular kidney, and of these 45 had more or less thickening of the valves. Again, of 215 cases of what appear in our records as primary heart cases, (the 192 given above figure as chiefly renal, so that the two series are distinct,) 34 were cases of granular kidney, and 9 of these were again examples of mitral stenosis, and all except three were mitral cases rather than aortic. I say rather than, because the aortic valves may here and there have been a little thick; but the mitral was the valve which was chiefly affected. These figures leave, I think, no room for doubt that chronic thickening of the endocardium is associated with chronic renal disease. I have been in the habit of teaching and demonstrating this for some years in our post-mortem room, and had thought that it was a somewhat novel observation, but I can no longer do more than say that it is an independent one, for others have now noted the same fact, and I am glad to be able to acknowledge that so late as yesterday I came across this passage, which I am almost ashamed to confess I had not noticed before:—"Disease of the aortic valves is common in the class of persons who acquire the gouty heart, and it is my strong conviction that mitral disease of the chronic sclerotic or contracting form found in elderly persons, especially in the form of regurgitation, is also found." Dr. Milner Fothergill, to whose work, "The Heart and its Diseases," I am referring, is there talking of the relation of heart disease to renal disease, and the thickening he attributes, and in part, no doubt, correctly so, to hypertrophy as a consequence of strain. It will be seen that I agree with him in his conviction, and contribute these data wherewith to support us, but I would supplement his remarks by saying that dilatation of the heart is common in these cases, and strain of some sort becomes all the greater, if, in addition to the greater dragging of a thickened ventricle, more forcible impact of blood against the flap, and the greater friction of the valves one against the other, there be added also the additional friction of a regurgitant blood-stream; and it seems to me to be probable that part, at any rate, of the chronic valvulitis is set up by the wear and tear of the regurgitant stream. But it may be said that the chronic thickening of the valve in old renal disease is due to an acute endocarditis toned down, and, if so, it would cease to have any bearing upon the question I am more particularly considering—viz., the influence of the anæmic heart upon valvular disease. I know it is taught in books that acute endocarditis is common in renal disease. Dr. Roberts, on the "Etiology of Acute Endocarditis," says, "Almost invariably the affection is due to some blood-poisoning, especially in connexion with acute rheumatism, but also in Bright's disease, pyæmia, &c."[2] Bright's disease is put first, after the greatly preponderating influence of acute rheumatism. Hayden,[4] after speaking of rheumatic endocarditis, says, "Next in point of frequency, it occurs, although not so often as pericarditis, in connexion with Bright's disease, and in this association it is usually fatal." Walshe,[5] too, writes, "Bright's disease, rheumatism, and pyohæmia are the main diathetic acute specific affections that clearly promote the occurrence of endocarditis." May I be forgiven for my presumption if I say these learned authors are all wrong. No, I will not be too dogmatic, lest, like a recent critic of the Lord Chief Justice on a legal question, I be set down as one of the most juvenile members of the profession; but I will say, May I beg your pardon, sirs, but the experience of Guy's Hospital and St. Mary's Hospital is completely against you. In our post-mortem records from 1866 to 1871, with an average of about seventy cases of Bright's disease annually, there is only *one* case of simple acute endocarditis in association with Bright's disease, and I state this on the authority of Dr. Hilton Fagge, who gives these figures in Reynolds's System of Medicine.[6] The late Dr. Sibson, in the same work, gives 297 cases of Bright's disease recorded at St. Mary's Hospital, and he only found one case of acute endocarditis. This is surely sufficient material to enable us to say that some mistake has been made on the point, and Rosenstein[7] seems to me to have expressed the facts correctly when he says, "Acute or chronic inflammation of the kidneys is not often the cause of endocarditis, but there are some recorded cases."

It is quite a mistake to suppose that acute endocarditis, in any but the most trifling proportion of cases, is present in renal disease; and I can only account for such an assertion by supposing that the chronic thickening of which I have made mention has been recognised as being frequently present, and that from it the pre-existence of an acute endocarditis has been assumed. But if so, it is an assumption quite without warrant. Chronic indurations are more often the parents of acute inflammation than are acute diseases the parents of chronic. So then I take the chronic thickening of the valves found in renal disease to be dependent in part upon dilatation of the ventricle and regurgitation of the blood through the valve, and so it is available as evidence in favour of a similar change being brought about in a

similar manner in the fatty heart of anæmia. I might, if I cared to do so, even claim the renal condition itself as acting upon the heart by way of the anæmia which exists in such case, but I do not do so because I am one of those who quite adhere to the view that high tension is in great measure the cause of the dilatation of the renal heart.

I must very hurriedly give one other additional link of evidence, which I ask to be interpreted with the light of the foregoing facts. It is the well-known observation that mitral stenosis occurs in overwhelming proportion in women. The drift of this fact will be seen at once from what has gone before. Mitral stenosis is a form of valvular disease to which a rheumatic origin is denied by many, and when this cause for it is taken away we are stranded in the unknown, unless, indeed, we are to rest content in the happy vagueness of poor Topsy that it "growed," should some such interpretation as I now suggest not come to our aid. A congenital origin is supported by some, but it seems to me hard to reconcile such an hypothesis with the fact that mitral stenosis is not common in childhood. But here I am at issue with writers upon heart disease, so I must give the grounds of my belief. I have notes by me of ninety-six or ninety-eight cases of heart disease in children which have occurred in my own practice, and in only one have I put down decidedly that the case was one of mitral stenosis. In five others the murmur was systolic, and only questionably presystolic, and in one or two others there was a rough first sound, and all the rest were cases of well-marked mitral regurgitation. I should therefore say that the clinical features of well-developed mitral stenosis are uncommon in childhood, though it is not uncommon to meet with cases where that condition is in all probability in the course of development; and for my own part I do not think there is any escape from the conclusion that some of the cases of mitral regurgitation in children furnish some of the cases of the mitral obstruction of adults. With regard, however, to the question of the rheumatic origin of mitral stenosis, I am quite convinced of the propriety of giving an affirmative answer to that question for the larger number of cases. Before we conclude that a form of heart disease is not rheumatic, we must take a much wider view of rheumatism and its relationship than is comprehended in establishing the previous occurrence or not of rheumatic fever in a particular case. A careful analysis of any large series of cases so examined will show without doubt that many contracted mitrals have rheumatic associations when superficially they have not appeared to do. Hayden, Hilton Fagge, and Dyce Duckworth all agree in this, and the latter has collected 264 cases from his own practice and that of the two beforementioned writers, and he finds that 60 per cent. were of rheumatic origin, using that term, as Dr. Duckworth puts it, in words which, I consider, very aptly chosen, "in a comprehensive but not inexact sense." I am obliged to say this much on the question *in limine*, though it is really a little beside the point, lest otherwise the objection should be made that, though mitral stenosis is thought by many to be non-rheumatic, that is not really the case. Upon the point in question it matters very little actually what view we take, because the rheumatic state is one which is accompanied, and often only disclosed, by a state of persistent anæmia. But I, nevertheless, accept the figures I have quoted, and we have yet remaining 40 per cent. of mitral stenosis, the majority of them, be it remembered, in women wanting an explanation of their origin. Dr. Fagge has suggested that possibly scarlatina or diphtheria may account for them, and I have been at some pains to follow up this clue, but I have not obtained any information to make me think that it can be a cause of heart disease in any but a very small proportion of cases. Mr. Shirley Murphy, a late resident medical officer of the Fever Hospital at Islington, and now medical officer of health for St. Pancras, tells me that of the cases of scarlatina admitted to that institution about 5 per cent. evolve a systolic bruit during the course of the disease, but that he only knew of one case in which it was anything more than temporary. My own experience, though less wide, is considerable, and it all points to the same conclusion—that scarlatinal endocarditis is not common, and any persistent heart disease from this cause is still less so. Moreover, we have the further difficulty to encounter, supposing we could admit that scarlatina was an important factor—viz., why scarlatinal endocarditis should fasten itself so all but exclusively upon women. Now, the suggestion I offer as the elucidation of this obscure point in the etiology of heart disease is this. Mitral stenosis is not uncommon in advanced renal disease, and lesser degrees of mitral thickening are yet more common. I consider the valvulitis to be set up by regurgitation of blood through the mitral, which in its turn is dependent upon the dilatation of the left ventricle, so common in Bright's disease. Both pathological and clinical evidence has been adduced to show that anæmia is associated with deteriorated cardiac muscle and dilatation. Anæmia is an extremely common affection both in women and children, and it is by no means very common in men. Is it then anything improbable that much of the mitral disease which is met with in women is the outcome of the mitral regurgitation which is seen so commonly in childhood and young adult women, and that this is dependent upon the dilatation of the heart in the course of the anæmia?

The question of treatment is quite a distinct one, and upon it I shall not enter further than to say that, impressed as I am with the probable truth of the view that I have put forward, I do not find that the anæmia of young persons is considered seriously enough. A woman comes to the out-patient room pale and panting with amenorrhœa; it is considered sufficient often enough to give her an ounce of compound mixture of iron three times a day, and she is packed off as only a case of anæmia which iron always cures. Our students, if they examine her at all, are only alive to a *bruit de diable*—a matter practically of very little moment, while the position of the impulse and the quality of the first sound are unheeded. But if it be true that a state of prolonged anæmia lays the foundation for permanent valvular disease, surely some very decided teaching on the subject should be inculcated in our text-books. It would, I think, be well, at any rate, to insist more absolutely on the necessity for rest in these cases, on the administration of heart tonics, such as belladonna and digitalis, and of sedatives, as bromide of potassium and hydrobromic acid; while in the matter of hæmatinic, experience has sanctioned the use of iron in a quite unequivocal manner. But I believe with Balfour that it should usually be administered in larger than the customary doses, and in such a form as to render them innocuous to the palate or digestion.

Weymouth-street, W.

THE TREATMENT OF RINGWORM.

BY WYNDHAM COTTLE, M.A., M.B., F.R.C.S., &c.,
SENIOR ASSISTANT-SURGEON TO THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS.

THE perusal of Mr. Smith's very interesting paper on the diagnosis and treatment of ringworm in THE LANCET of Jan. 10th, 1880, and following numbers, has afforded me much satisfaction. It is gratifying to find that an independent observer advocates the same principles in the treatment of this disease that I have already laid before the profession, and that he has been led to adopt those views by the same line of reasoning that I then urged in their behalf. It seems to have escaped Mr. Smith's notice that in a paper read before the Dermatological Section of the British Medical Association at the meeting of the Association at Cork in August last, I advocated the treatment of ringworm in recent cases, and in certain situations, by the ordinary parasiticides, and more especially by the use of salicylic acid, while I recommended the application of croton oil to the more inveterate seats of the disease, so as to produce a deep pustular rash. As Mr. Smith seems to me from the description he gives to carry this treatment to an unnecessarily severe extent, I may perhaps venture to recapitulate my mode of procedure, which has been arrived at after a long series of experiments.

I found in practice that ringworm readily yielded to treatment (1) when situated on the parts of the body not occupied by deep-rooted hair, (2) when it occurred in infants, (3) in recent cases in healthy children. I accounted for this clinical feature of the disease in the first two classes of cases by the non-existence in them of deep hair-follicles, and in the third class by the fungus not having had sufficient time to spread far into the hair-follicles, and to its having fallen on a soil not congenial to its development. I also constantly encountered cases in which, after the most energetic and assiduous treatment, the disease still flourished in spite of the measures employed. I concluded that this persist-

Digitized by Google

ence was attributable to the parasite having invaded the deeper portions of the hair root, and that the remedies employed, though they had cleared the superficial structures of the fungus, had failed to reach it in its more remote situations. In long-standing examples of ringworm the parasite prevades not only the epithelium and hair, but also makes its way to the bottom of the hair root, so that the microscope detects it at the very extremity of the hair bulb, and it is allowable to infer that it also penetrates that portion of the hair root which remains behind when the hair is extracted. That it abounds in the lining membrane of the follicles through its whole extent can be often demonstrated in those cases where, loosened by inflammatory action, the follicular sheath can be extracted with the hair. It is this propensity of the fungus to extend itself deeply beyond the hair that renders the most careful epilation inefficient to eradicate the disease, since, even when most successfully performed, it can only remove the hair and not its contiguous structures.

In applying remedies for this complaint, it is necessary by some means to bring them in contact with the deep-seated parasite, and we may be quite sure that if we can succeed in destroying it when buried beneath the surface, that which is superficially situated will have perished also. I thought that a penetrating subtle fluid was more likely to find its way into the hair-follicles than a thicker fluid or an ointment, unless the ointment were most thoroughly rubbed in—no easy matter on the tender scalp of a delicate child. I find that such is the case. I believe that strong solutions of perchloride of mercury are of such recognised efficiency in ringworm from the amount of alcohol that is usually prescribed in these lotions aiding the penetration of the salts they contain. Such solutions of mercury have been known to produce disagreeable effects. After many trials, I find no one substance so efficacious and convenient as salicylic acid. It is a parasiticide, a slight irritant, and exercises no toxic influence. I have prescribed it largely as an ointment, and also as a lotion; and it may often be combined with other agents with benefit. It is soluble in alcohol or rectified spirits of wine. However, we have a large number of bodies at our choice that act excellently in the way I mention—e. g., turpentine, or alcohol itself, or benzine, or the purer forms of the paraffin of commerce.

Many observations have taught me that in those portions of the scalp where kerion or an abscess supervenes, on the recovery of the part from such accident, no trace of ringworm was to be found, and that the sites of such abscesses remained free from disease, oases of health in the midst of the implicated scalp around.

Pus and the inflammatory process which gives it birth have long been recognised as inimical to fungoid life, and I concluded that in these cases of kerion the parasite had perished owing to its having been subjected to the action of the products of inflammation in its more profound and inaccessible situations. I saw that if I could succeed in producing a like condition I might hope to obtain a like result, and I have found that it is so. I thought that it would be sufficient for my purpose to set up a pustular rash involving the tissues to the depth of the hair-follicles, and that the formation of a subcutaneous abscess was unnecessary.

The various irritants that may be applied to the skin are wont to be followed by very dissimilar effects: for instance, mustard or heat will usually produce a superficial erythema; cantharides a sub-epithelial effusion; chrysophanic acid an erythema with a subcutaneous œdema; the more powerful chemically acting agents, as the caustic alkalies and strong acids, a local necrosis or slough; while localised suppuration, e.g., a pustular rash, most readily follows the application of antimony, chloride, or croton oil, but the antimony salt is apt to give rise to sloughing.

My earlier attempts to cause suppuration in the portions of the scalp occupied by inveterate ringworm were made with sulpho-carbolate of barium, an irritant and parasiticide combined of no mean potency, but I abandoned its use in favour of croton oil, since I found this agent more certain and rapid in its action, and able to produce a more perfect crop of pustules.

The method I am now using is the following:—

In recent Cases, &c.—In ringworm of the body, in infants, and in cases of recent origin on the scalp in older children, after the hair has been cropped short around the affected spots (if on the scalp), and the part well scrubbed with soft soap to insure the removal of crusts, &c., I direct the affected part to be thoroughly soaked and rubbed, three times daily, with a solution of salicylic acid in alcohol (thirty grains in an ounce), or with benzine, &c. The diseased hair, crusts, &c., must be cleared away as often as they are reproduced. This is generally all that is required, such cases as those indicated readily yielding to these measures. If any patches show a tendency to linger, they may be painted with glacial acetic acid, or blistering fluid, or carbolic acid. Solutions of salicylic acid in alcohol of themselves, however, set up considerable skin irritation, and sometimes a crop of pustules.

Chronic Ringworm.—In chronic ringworm of the scalp this treatment, however, will not always end the case, and it then becomes advisable to have recourse to the formation of a pustular rash. To effect this the tardily mending spots should be freely painted with the linimentum crotonis (B.P.) I find this preparation more efficient than croton oil itself, I fancy owing to the spirit it contains favouring its penetration into the follicular orifices, and bringing it into more close contact with the skin. Washing the part with alcohol or ether before applying the croton oil makes its action more certain, and, I believe, for the same reason. If the croton-oil liniment does not produce suppuration, I repeat it, and, if necessary, blister the skin before putting it on; or a liniment containing more croton oil may be used. The parts become covered with a yellow crust, which should be removed as soon as practicable by poulticing or softening with oil. Most of the diseased hair will come away with the crusts. Any that remain should be carefully removed with forceps, and the search for them constantly renewed. After the removal of the scabs and hair the salicylic acid should be freely and frequently applied. It is practically of advantage to produce suppuration on one side of the head only at one time, and to allow the parts to soundly heal before the other side of the head is attacked, in order that the child may be able to rest its head on the pillow without inconvenience.

The rapid drying of the croton liniment prevents the risk of the transference of the croton oil to the face, &c. It is not necessary to produce a real subcutaneous abscess or kerion to effect the destruction of the parasite even where deep in the skin. A copious pustular rash is all that is required for the purpose, and this less severe treatment may be carried out over considerable tracts of the scalp at the same time. The production of pustules by croton oil is neither adapted to, nor requisite in, cases where scalp irritation already exists.

In all chronic cases of ringworm suitable internal treatment should be adopted, for it is of the first importance to remove that condition of nutrition, whatever it may be, that favours parasitic growths on the skin.

A few days ago a most striking case came before me. A little girl, with other members of her family, had been affected with tinea tondens for nearly two years, and subjected to much careful treatment. To one particularly obstinate spot, the original seat of the disease, I had applied croton liniment three weeks previously. Microscopic examination detected conidia in several of the hairs taken from other portions of the scalp, while in the hair that remained where the croton oil had been used, though showing signs of inflammatory action, no vestige of the parasite could be found.

Although the deep abscesses sometimes occurring in cases of ringworm cause destruction of the hair roots and permanent baldness, I have not seen any such result follow the use of croton oil as I employ it. The application is painless, and the only ill result is the discomfort of a pustular rash on the part. We are all familiar with its effect when applied to the chest as a counter-irritant. Its action when used on the scalp is similar, and causes a like amount of inconvenience. The advantages of this method of treating ringworm are—

(1) It is comparatively painless, easy and agreeable to carry out; and if salicylic acid be employed there is no unpleasant odour.

(2) No poisons are used, and therefore no fear of absorption exists.

(3) The inconvenience of a pustular rash on the scalp (if it becomes necessary to resort to the croton oil) is less irksome to the child than the acute pain of the ordinary vesicating remedies.

(4) No permanent loss of hair results.

(5) Many intractable cases rapidly mend when so dealt with.

HUMAN AND ANIMAL VARIOLÆ: A STUDY IN COMPARATIVE PATHOLOGY.

BY GEORGE FLEMING, F.R.C.V.S.,
ARMY VETERINARY INSPECTOR.

(Continued from p. 445.)

IT is curious to note that, in 1863, the same (Lyons) Commission was desirous of discovering whether small-pox could be transmitted to animals, and they made a number of inoculations, but all these apparently failed. Subsequently the animals were inoculated with human vaccine, and the same negative result followed. But it was never suspected then that the vaccination failures were due to the previous variolation, supposed to be ineffective, and it was concluded either that human vaccine takes with difficulty on the bovine species, or the animals experimented upon had previously been affected with cow-pox. It would thus appear to be demonstrated in the clearest manner that variola and vaccinia are related, or rather opposed, to each other in the bovine species, in the same way as they are in mankind. The negative results following variolation in animals which had been successfully vaccinated, was a crucial test of the soundness of this demonstration. Three animals — a cow and two calves — were variolised and vaccinated at the same time, the small-pox matter being inoculated on the left side of the vulva, the vaccine lymph on the right. In the three there appeared on the right side the very characteristic vaccinal eruption, and on the left the typical papular eruption engendered by variolation, as in two of Ceely's experiments.

To prove whether, after all, the papular eruption produced by small-pox virus might not be a mild kind of cow-pox, the feeble eruption of which could, by a methodical cultivation on bovines, become more developed, its transmission was attempted to other cows; for the eruption differed from human small-pox in being always local, while the papules, neither in volume, external characters, nor development, bore the slightest resemblance to that disease; whereas by its localisation, development, and the absence of general phenomena, it did somewhat resemble cow-pox, though in other respects it widely differed. Three calves inoculated from the fully-developed eruption with all the care possible, showed still less local alteration, while with a young bull it entirely failed, and subsequent vaccination was most successful. From this it was concluded that the variolic virus, instead of being cultivable in the ox tribe, loses its activity, and scarcely produces any effect in the second generation.

Was this eruption, then, merely that of modified small-pox? The results of small-pox inoculation on man are nearly as well known as natural small-pox itself, and there could be no mistake in the result if this bovine eruption was successfully re-transmitted to the human species. With the object of proving this, an unvaccinated infant, three months old, was inoculated with a very small quantity of serosity obtained by scraping some of the papules on a variolised cow. Four days afterwards on one of the punctures a pimple was noticed, which soon assumed all the characters of a vaccinal pustule; and in nine days it was large, umbilicated, surrounded by a red areola, very irregular at its periphery, and covered on its surface with a kind of small vesicle; it was *aquarellée*. When opened, only a very small quantity of fluid could be obtained from it to inoculate the arm of another child. Next day the infant was feverish and ill, and on examining it carefully a great number of small pimples were found on the face and trunk; on the following day these were fine variolic pustules, the majority of which were umbilicated, and formed a quasi-confluent eruption. In a week the pustules were desiccating and the child recovering.

The child inoculated from this one had three punctures on each arm, all of which had a *bouton;* in eight days from inoculation the development of these was complete, and they so closely resembled vaccine pustules that several competent persons asserted they were such. The next day two small vesicles appeared around each pustule, and in four days some small-pox pustules (about fifteen) showed themselves on the face and other parts of the body. The child did not appear to be unwell, and the slight general eruption disappeared rapidly without leaving any traces.

Thus, in a second generation in the human species the variolic virus from the cow had produced much better local effects than in the first, and incomparably feebler general effects. What might it have been in a third or a fourth generation? The fear of creating an outbreak of small-pox in the hospital brought these transmissions to a conclusion. But even the very decided results obtained did not suffice to satisfy the Commission. After all, the eruption on the children, though it appeared to be due to nothing more than direct inoculation of human small-pox, might be only generalised vaccinia, which some authorities assert does occur. But such a confusion between the two diseases was proved by the foregoing experiments to be impossible. Deposit humanised vaccine beneath the skin of a calf, and an eruption of unmistakable vaccinal pustules is obtained, which can be indefinitely transmitted to animals of the same species. But inoculate with small-pox virus, and there is only an insignificant papular eruption, the transmission of which from one calf to another is extremely difficult, if not impossible.

To meet any objections, however, that might afterwards be raised in this respect, two calves—a male and a female—were inoculated with virus from the last-mentioned child. In seven days, in both animals there was a somewhat microscopic papule at the seat of puncture. One of these papules —on the scrotum of the male—was used for the inoculation of another calf, but the result was absolutely negative; proving, in the first place, that the virus transferred from small-pox infected man to bovines, and carried back to man again, is still small-pox virus, and is not converted into cow-pox virus; and in the second place, that small-pox is not vaccinia.

Some experimenters had previously attempted to inoculate the horse with human small-pox, but met with only negative results. The Lyons Commission undertook several series of experiments on this animal, somewhat similar to those on bovines, and arrived at analogous conclusions. The horse was as susceptible of inoculation as the ox tribe, and the same phenomena were produced; but the papular eruption developed at the punctures was so evident, that no doubt whatever could exist as to its presence and its specific character. Indeed, it was so greatly developed that inexperienced observers might have mistaken it for horse-pox, particularly at the commencement. But in horse-pox, as in cow-pox, and even more so in the former, there is a secretion and the formation of a crust; but these are nearly, if not quite, absent in the inoculated variola. The same experiments were made in vaccinating after inoculation, and *vice versâ*, as with the ox, with exactly the same results. The horse was also proved to be as little adapted to the cultivation of small-pox virus as bovines. Three children were inoculated from the horses, and though the phenomena observed are of considerable interest, yet I cannot allude to them in this place, but will merely remark that the patients offered symptoms, mild in their degree, similar to those which follow small-pox inoculation. The result arrived at was that, as with the ox, the horse returns the small-pox virus to man just as it receives it. But the production of variola in the three children was followed by a mild attack of natural small-pox in an unvaccinated infant in the same room; and its mother, who had been vaccinated as a child, was soon after affected with a true varioloid eruption, with fever and other signs of general derangement.

The variolic virus obtained from the equine species was cultivated in mankind to the fourth generation, and produced a local and somewhat modified general eruption. From the second generation horses were inoculated, and only the typical variolic exanthem was developed—never the unmistakable horse-pox. Transferred from the horse again to the ox, in order to be assured that the eruption engendered by the cultivation in man of the small-pox virus, transferred originally from him to the horse, was not that of vaccinia, another series of experiments on cattle was instituted. Many horses were inoculated, and the conclusion arrived at was, that when carried to and cultivated on the cow, after producing in mankind, for several generations, local eruptions altogether identical in appearance to vaccinia, the variolic virus of the horse only develops the phenomena of variola, as in the bovine species.

Thus it will be seen how earnestly and exhaustively the Lyons Commission accomplished its task, and what con-

Digitized by Google

clusive results were arrived at. We can find no evidence anywhere in their report that the small-pox virus was merely deposited in a little pouch, and re-inoculated from it again. On the contrary, marked phenomena were developed in every instance, and the crucial manner in which one series of experiments was made to test or control the results arrived at in another, left no room for doubt or error. Many of the experiments were original, particularly those on the horse, of which there were nine series.

The Commission, in closing its report, refers to the positive experiments of Thiele and Ceely as opposed to their negative ones—experiments which, they say, were extremely important, and which, notwithstanding the erroneous conclusions of their authors, will always hold a considerable position in science. Thiele and Ceely, they add, each experimenting independently, succeeded in giving cow-pox to cattle by inoculating them with human variola, and this cow-pox became the origin of an excellent vaccine, which was cultivated in infants for more than twenty years, in certain parts of England, Germany, and Russia, and has passed through a great number of generations. It is not denied that they succeeded in obtaining positive results from their attempts to inoculate the cow with variola; but that which is astonishing, after the results arrived at by the Commission, is not these positive facts, but the negative results which other experimenters almost unanimously acknowledge. But had Thiele and Ceely well observed and closely interpreted the facts the manifestation of which they elicited? Is it really true that they succeeded in converting variola into vaccinia? The Commissioners think not, and are of opinion that the children they inoculated with their variolic vaccine had nothing else than small-pox, the same as the children in the Hôpital de la Charité. This kind of inoculation is now-a-days well known, and it is really not necessary to have recourse to a new inquiry to appreciate its signification with regard to the doctrine of identity of variola and vaccinia. What did Thiele and Ceely communicate to the cow? Was it cow-pox? It was nothing of the kind. The excellent drawings made by the Commission representing the characters of the eruption produced in the ox by variolisation, are evidence that there is not a very distant analogy between cow-pox and the results of small-pox inoculation. The Commission had not seen Ceely's drawings, consequently it did not know if they differed from those it produced; but it ventured to assert that if they differed from these, and represented eruptions of veritable small-pox, the artist had not been absolutely inspired by the real truth. Nothing that Thiele and Ceely had done in inoculating the cow with variola could have produced anything resembling cow-pox, not even the extensive variolous wounds that were obtained, by making long and deep incisions in the skin, and pouring large quantities of small-pox virus therein. But if their cows did not have cow-pox, how were these two experimenters able to vaccinate children with the matter from them? The cows could not give that which they had not, says the Commission; and this is why, it affirms, the children operated on by Thiele and Ceely received small-pox; and it was nothing but small-pox which was developed on all their inoculated subjects. It was variola such as the Commission had seen in its own experiments—variola limited sometimes to the local primary eruption, and quite like vaccinia, variola often accompanied by a secondary eruption, which gave it its special physiognomy. Between the descriptions of the two experimenters, and those given by the Commission as to the eruptions which offered benignant characters, there was not the slightest difference; and if the children inoculated by the latter were affected with variola in consequence, so should those of Thiele and Ceely. If the virus of the latter is really vaccine, then it should give cow-pox to the cow at once, like the Jennerian vaccine; if not, then it will only produce the papules of the variolic eruption.

With regard to the pretended innocuousness of Thiele and Ceely's so-called vaccination, reported to be as absolutely harmless as true vaccination, the Commission did not believe that it was due to the passage of variolic virus through the bovine species, as it was found that it underwent a considerable attenuation in the organism of the ox, and could only be propagated through a very limited number of generations; but when returned to the human species, it appeared to regain all its activity. When first transmitted to man from the ox or horse it caused a very abundant, almost serious, secondary eruption, while all the children inoculated from this transferred virus had a discrete and almost insignificant eruption. The Commission clung to the opinion that Thiele and Ceely only practised variolation, instead of vaccination; and they therefore gave the children they inoculated better protection than if they had been vaccinated, if they did not expose them to more dangers. A question of much interest is that of the innocuousness of mediate variolation, and if it be proved to exist the Commission thought recourse would at once be had to Thiele and Ceely's method when good vaccine lymph could not be procured. But there is the grave danger of *contagion;* for in passing through the organism of animals the small-pox virus loses none of its infectious properties. Experience has only too well proved this, and this is why mediate variolation, like direct variolic inoculation, would create, if it became generalised, permanent centres of infection, which would soon cover nearly the whole globe. This danger does not exist with the vaccine virus; and therefore it is that vaccination will always hold the first place in the prophylaxy of small-pox.

I think I have now offered sufficient evidence of a clinical and experimental kind to prove that the variola of man is not that of the cow, and that by no possible means can the virus of the one be transmuted into that of the other. The bovine organism cannot reduce a general eruptive disease, due to an exceedingly infectious virus, to a merely contagious and very mild disorder, accompanied by a limited local eruption. No more can the organism of the sheep; for the many experiments which have been performed with the small-pox virus have not modified it in any respect, and it has retained all its original infective properties. Neither can the human organism transform vaccinia into variola, for had this been possible, surely the millions of vaccinations which have been made under every condition during this century, would have afforded us some evidence of such capability! If vaccinia cannot be transformed into variola, as little probability is there that variola can be changed into vaccinia.

Years ago the veterinary professor, Hering, had repeatedly inoculated the cow with vaccine lymph, and found that this gave it renewed potency. The veterinarian Numann made similar observations, and incidentally noticed that the bull is as susceptible as the cow; also that the horse and ass are, but that their vaccine, when re-transferred to man, is slower in its action than that from the cow. Besides, the transmission of vaccinia by inoculation from cow to cow is accomplished without any difficulty, and the successive transplantations of the same lymph does not appear to have any influence on the development of the resulting pustules. In the very numerous experiments of Depaul, it was found that the pustules of the last inoculated animal offered the same characters and dimensions as those of the cow first inoculated. How is it, then, that the vaccine virus can be transmitted for generations from cow to cow, cow to horse, or horse to horse, retaining all its primitive potency, and even becoming revivified when carried from the human species; whereas the virus of human variola only produces a local papulation in them, quite unlike vaccinia, which can rarely be reproduced more than two or three times, and which always develops small-pox when inoculated again on man?

From all the evidence I have adduced, there is every reason to think that those experimenters who imagined they had produced vaccinia by inoculating the cow with variolous matter, were in error; and if it be true that they employed the virus from the cow in vaccination, then if the above evidence be accepted as trustworthy, there is reason to believe that it was merely the small-pox virus returned again to the human species, just as it was obtained from it. There are instances on record in which the most serious results have followed the attempts of imitators of Gassner, Thiele, Ceely, and Badcock—outbreaks of small-pox resulting. Have the widespread epidemics of small-pox in recent times been to any extent due to these inoculations of the cow with human variola, with the view of obtaining vaccine lymph?

However these questions may be answered, one thing must be looked upon as definitely settled, and that is that small-pox is not cow-pox; they are independent and distinct members of a family group, and can no more be transmuted or converted into each other than can two dissimilar plants or animals. The error in supposing that they are transmutable—or, rather, that small-pox can be converted into vaccinia was due, in all probability, to inacquaintance with experimental methods, an inability to appreciate the results of experiments, and imperfect knowledge of animals and animal disorders. No control experiments were resorted to, as with those of the Lyons and Turin Commissions, and what may have looked like vaccinia was accepted as vaccinia. In no

Digitized by Google

other way can I account for what must now be considered a grave error.

In insisting upon the correctness of this view, and urging its importance not only with regard to comparative pathology, but also the prevention of an odious and destructive human plague, I am well aware that I am placing myself in an attitude of antagonism to very high and estimable medical authorities in this country; and especially Sir Thomas Watson, who in a paper in the *Nineteenth Century* (which paper has been recently republished in a small volume) says, "The truth is, that the vaccine disease is really small-pox rendered mild by passing through the system of the cow; the great object of inoculating the small-pox was to produce a benignant form of the disease by diminishing the number of its pustules."

I have shown that there is no relationship between the prevalence of cow-pox and small-pox, and that the one may, and does, prevail in localities, and at times when and where the other is not seen. In Denmark, for instance, small-pox is all but extinct, and yet cases of cow-pox are far from rare. The difficulty experienced by those who believe in the unity of the two diseases, in accounting for this circumstance, is attempted to be got over in various ways. Bollinger, for instance (*Sæmmburg. Klinischer Vortrag*, No. 116), thinks that cow-pox owes its existence sometimes to humanised vaccine—the most extended and extensive of all the forms of variolic contagium, he says. "We must look," he writes, "to humanised vaccine as the source from which the greater number of cases of bovine variola have their origin." A few instances are certainly recorded in which, apparently, accidental infection of cows by recently-vaccinated people has occurred. Osiander alludes to the case of a cow which was so infected by a boy who had been vaccinated a short time previously. In the Prussian Veterinary Reports on Contagious Diseases among Animals for 1870-71, Koch reports that the vaccination of the people on a farm occasioned the infection of the cows with cow-pox, and in the same reports for the following year an outbreak of vaccinia was announced as having taken place among a lot of cows, consequent on the revaccination of three dairymaids. In three weeks the disease appeared, and gradually extended, so that in fourteen days of twenty-six cows only three escaped. The majority of the cows had only a few pustules upon the teats, but others had a number upon the teats and udder. In the same reports for 1874-75, Damman describes an outbreak of vaccinia in several sheds in the Rugen Kries, while in the district many children had been vaccinated, and the vaccine vesicles were fully developed. Schneider informed Bollinger that in 1876, after several children in a certain locality had been vaccinated, four cows in two sheds in the same place became affected with cow-pox; two dairymaids became accidentally inoculated from these, and one of the women communicated the infection to her children, who had not been vaccinated. Reiter also told Bollinger that in cowsheds where he vaccinated cows, several non-vaccinated animals showed the characteristic indications of the disease, which ran its course in the ordinary manner.

Though there is no reason to believe that cow-pox is infectious—i.e., virus *volatile*,—yet there is as little reason to deny that cows may not become affected through contact with newly-vaccinated persons, provided some vaccine lymph obtains access through a sore. But it is evident that this chance inoculation will not account for many, if any, of the reported cases of cow-pox.

(To be continued.)

FALL FROM A HEIGHT OF OVER SEVENTY FEET; RECOVERY.

By STEPHEN KARTULIS, M.D. BERL.,
HOUSE SURGEON TO THE GREEK HOSPITAL, ALEXANDRIA.

THE happy result of a fearful accident, attended with such severe injuries as shown in the following case, is, I believe, sufficient to justify me in sending it to THE LANCET. So tremendous a fall without immediate death is a rarity of the greatest interest, to say nothing of the satisfaction of seeing the case thoroughly cured in so short a time and with the most simple means a surgeon can command.

In the afternoon of 1st June last, an English boy in his eighth year, accompanied by an elder brother, a sister, and an Arab servant, were playing on the terrace of a third-storey house (one of the highest in Alexandria), and not being able to fly a kite they had with them, clambered up on the roof of a wash-house. The boy wishing to cross over a beam which connected the front with the back part of the building, slipped and fell from the top to the basement on a granite pavement, a height of seventy-one feet three inches (carefully measured). I was immediately summoned, and on reaching the house a few minutes later was astonished at finding him still alive and conscious.

On examination I found, first, that both bones of the leg were smashed in the middle, so that the limb hung from the bed on which the boy was placed like a loose piece of the body. There was a sinus the size of a shilling above the fractured bone, whence issued a slight hæmorrhage. The femur was broken very irregularly about three inches above the condyle, so that it caused a deformity of the thigh; unfortunately it was not indicated, and the hour being late, and Sunday evening, it was impossible to obtain the assistance of another doctor, consequently the necessary bandages, &c., were not sent for. However, I made from the bedclothes sufficient bandages, and cut out of a piece of wood something like a Liston splint. This was done to get the fractured parts in as good a position as possible, leaving it to the following morning, if considered necessary, to make a more efficient bandage with the assistance of another surgeon. I nevertheless paid great attention to bringing the fractures to their proper bearings, but naturally I found much difficulty, unaided, in extending and dressing. I applied the splint to the outer part of the limb and bound it from the toes to the abdomen, leaving a fenestra on the sinus in the middle of the leg for the purpose of applying antiseptics. I washed it with a solution of carbolic acid, 5 to 100, and dressed it with gauze, &c. Ordered eight grains of calomel to be given at once, and an ice-bag to be applied constantly to the head.

June 2nd.—The boy had passed a restless night with convulsions. On a consultation with Drs. Mackie and Dove, of the Deaconesses' Hospital, it was decided to leave the setting as it was, to darken the room, and enjoin absolute rest. Bromide of potassium and ergotin to be given at intervals. Temperature, 39° C.; pulse, 160. Evening: temperature, 38·07° C.; pulse, 150.

4th.—Passed a restless night with delirium and convulsion. Formation of thrombus in the sinus; no pus. Elevated limb in a cradle, extending it at same time. Temperature, 37·05° C.; pulse, 130.

5th.—Better; without fever. Wound looks very well. No pus. Patient good-tempered.

6th.—Much better. No fever.

From the 6th to the 11th the patient progressed in health, and the wound granulated. On the 8th and 9th there was a little fever (38° C.) On the left temple, where there had been a contusion, a hæmatoma was formed, which I opened. On the 13th diarrhœa came on, which lasted for three days, and then passed off after the exhibition of bismuth. The general condition of the child was now satisfactory. He had no pains in the limb. The wound had healed; but there not being in the house all the commodities necessary for the requirements of such a case in absolute rest, a good deal of urine saturated the dressing, which became very offensive. I therefore determined to change the dressing. This state of things was indicated before the bones were united, and now that the time had arrived to bring them into a good position, and having obtained the valuable aid of Dr. Zancarol, of the Greek Hospital (Dr. Mackie having previously left for England), we took off the dressing, and applied a plaster-of-Paris bandage. This operation was carried out with great care, due respect being paid to the short lapse of time since the accident.

From this date I ordered a generous diet, and after thirty-three days removed the plaster bandage.

On examining the parts I found the fractures united, and with the exception of a slight curvature in the leg it was as sound as in its normal condition. In measuring, however, the length of both limbs, the injured one was found to be about half an inch shorter than the other.

On the 24th July the boy could hobble about with a crutch with slight assistance. Ordered an orthopædic apparatus for support of the limb.

On the 15th November the boy was racing across the playground of his school with six other boys of about the same age, and came in third.

AMYLOID DEGENERATION.

BY GEORGE BUDD, JUN.

(Concluded from p. 324.)

EXPERIMENT 6.—Having dissolved a quantity of lardacein in a strong solution of ammonia, I subjected the resulting liquid to gradual evaporation at a low heat. At the end of a day the fluid had become reduced to a fraction of its former bulk, and a thin scum separated upon its surface, consisting of precipitated lardacein. I placed a portion of this scum upon a slide and treated it with iodine, whereupon it immediately exhibited the mahogany red reaction—a result seemingly sufficient in itself to disprove Dr. Dickinson's doctrine of acidity, seeing that the reaction persists after such a prolonged treatment with strong ammonia.

Reviewing the results of these experiments, it will I think be concluded that Dr. Dickinson's theory has been founded upon a misinterpretation of a series of simple chemical combinations; for the iodine reaction is not, as he thought, due to any acidity of the waxy substance. (Experiments 1, 2, 3, 6.)

But to revert to another matter. I have said that the analyses hitherto made do not denote the composition of the simple infiltration, but rather that of the infiltration plus the cells affected. To this sum I must now add a variable quantity of unaffected cells also. Before attempting analysis efforts are made to remove unimplicated structures. The waxy organ is cut into small pieces, and these are subjected to digestion. Each piece consists of a congeries of countless cells, some waxy, others not. The unaffected cells upon the surface may be dissolved away, but those beneath will be protected from digestive action by the lardaceous cells around them, and will play a not unimportant part in the composition of the mixture when analysed.

The formula then which has been hitherto supposed to represent the composition of the infiltration is an erroneous one, and in the absence of better evidence pertaining to its elementary constitution we must examine the substance from another aspect. The brown iodine reaction exhibited by lardacein points to some possible relationship to members of the starch group. Now there is a starchy substance (dystropodextrin) normally present in the blood which agrees with the infiltration in its most essential characteristic—viz., its total disregard for all fermentative influence. That starchy substance is a nutrient compound, and is in virtue of its stable constitution just such a body as might under certain conditions prove difficult of assimilation. Moreover, waxy infiltration exhibits a peculiar predilection for that zone of the liver lobule which regulates the formation of this alimentary dextrin. Of course, it may be that these are merely coincidences, but if so they are remarkable ones.

The morbid history of the waxy cell is unknown, and all conjectures in this direction must be speculative. But it would seem to me in the highest degree improbable that the process is one of simply mechanical addition of deposit to the cell; for the latter is a living structure and vital processes are not usually of so simple a nature. It is at least possible that the infiltration may undergo assimilation in the centre of the cell where the vitality is great, and that what appears to be a cell distended and surrounded by deposit is in truth an engorged cell within a shell of unassimilated infiltration, the latter like a layer of protective paint yielding the external phenomena of the mass, but, since it is present in only comparatively small quantity, giving no conspicuous indication of its presence upon ultimate analysis. This, of course, is speculation; all I wish to do is to call attention to the fact that not only does the reputed formula of the infiltration represent a mixture, but possibly a mixture in which the unaltered deposit may be present in only very small quantity indeed.

I had intended, in conclusion, to give a brief summary, but I find that I am unable to do so without unavoidably repeating many sentences and expressions used in the course of this paper, and I do not wish to encumber the communication with tedious reiterations. I would, however, again call attention to Experiments 1, 2, 3, and 6, as I believe they disprove in a decisive manner Dr. Dickinson's theory of acidity.

Edinburgh.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morbosum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GUY'S HOSPITAL.

SURGICAL CASES ILLUSTRATING WOUND TREATMENT AND REPAIR.

(Under the care of Mr. BRYANT.)

THE following concludes this series of interesting cases:—

Rupture of Gastrocnemius; Hæmorrhage into Muscle; Recovery after Incision. (From notes taken by Mr. L. W. Stephens.) — John M——, aged twenty-eight, was admitted into Job ward on Nov. 10th, 1879. Seven weeks before admission, while carrying some deals, he slipped, and, to save himself from falling under them, threw them from him, and felt that he strained the calf of his leg in so doing. He continued to work, feeling occasionally pain until Nov. 4th.

On admission he seemed a strong, healthy man, and complained of pain in his calf, which was swollen, tense, and hot. There was no œdema superficially. The internal saphena vein was full, and somewhat distorted. The right calf measured fifteen inches and a half, against fourteen inches for the left.

On Nov. 13th fluctuation was detected, and an incision about one inch long was made over the inner belly of the gastrocnemius muscle four inches below the head of the tibia. About an ounce of serum escaped, and a large blood-clot was detached by the finger, of the size of a hen's egg. The wound was washed with iodine-water, and terebine was applied, with a pad and bandage. No suppuration followed, and the temperature did not rise above 98·6°. The man was discharged cured on Dec. 2nd. The blood had been extravasated into the body of the gastrocnemius muscle.

Genu Valgum; Division of Femur; Recovery. (From notes taken by Mr. Duckworth.) — Charles M——, aged four, was admitted into Lydia ward on May 15th, 1879. The child was a fine, healthy-looking little fellow, but was knock-kneed. While in a truck he fell out upon his forehead, and was brought to the hospital with an oblique incised wound just above and at the middle of the left eyebrow.

The wound was cleaned and strapping applied, and on May 31st it was completely scabbed over.

On June 3rd operation for genu valgum was performed under chloroform. An incision about an inch and a half above the knee was made on the inner side of the right thigh with a long scalpel, vertical in direction, and three-quarters of an inch in length. A small saw was introduced into the wound before the withdrawal of the knife. The saw was turned so as to be at right angles to the femur, which was then sawn about three-quarters through, and the bone snapped. There was scarcely any bleeding, and no vessels were twisted. Terebine-oil dressings were applied, and a splint placed on each side of the limb, which was put straight by pads of lint.

On the 23rd the wound was completely healed.

On July 14th the splint was removed. The bone had united and the leg was straight, but the patient could not flex the knee more than 30° without pain. On the 26th a felt splint was applied. The boy could walk very fairly. The left foot was everted in walking.

The temperature never rose above 98·5° F.

Ovarian Tumour; Ovariotomy; Recovery. (From notes taken by Mr. Duckworth).—Martha B——, aged fifty-one, was admitted into Lydia ward on May 28th, 1879. She was a healthy married woman and mother of seven children, all alive and healthy, the youngest ten years old. About a year before she first noticed a swelling in her abdomen, and felt on her right side a hard movable lump about the size of a teacup. The lump was slightly painful on pressure. When she laid upon her left side she felt it fall to the left. The lump gradually increased in size until two months ago, when it rapidly grew larger.

Digitized by Google

On admission the abdomen measured just below the umbilicus forty-one inches, and two or three inches lower down about forty-four. Across the middle could be felt a very large, irregular, hard mass, very movable and painful on pressure on the right side, presenting across the centre a vertical depression in a line with the umbilicus. No fluctuation was discernible. There was resonance in the flanks, dulness in front. A tympanitic note was audible over the epigastrium. No fluid thrill could be felt. The skin presented a pitted and longitudinally wrinkled appearance from over-distension in pregnancy. The urine was dark-yellow, thick, and clouded with mucus, with a good deal of phosphatic deposit, and no albumen.

On June 9th the patient was examined by Dr. Galabin. The uterus was found in the normal position. A sound passed three inches, and the uterus was freely movable by its means. Tumour just reached in front of cervix, and did not descend into the pelvis, and did not appear to be closely connected with the uterus. It was thought the tumour was a polycystic ovarian, but possibly a pedunculated fibro-cystic tumour.

On June 11th ovariotomy was done under chloroform. A manifest thrill could be made out from side to side. An incision was made along the linea alba five inches long, through the skin and fat. One vessel was twisted and the other tissues were divided on a Key's director, and the cyst exposed. The cyst bulged through the incision and was tapped with a trocar and cannula, and about six pints six ounces of a dark-coloured, porter-like fluid escaped. The tumour was monocystic and thick-walled, and connected with the right ovary. The pedicle was clamped and the tumour removed without the loss of any blood. A silk ligature was fastened behind the clamp, and the clamp left on. The intestines which appeared during the operation were gently pushed back and omentum replaced over them. The wound was closed with ten silk sutures, and pads of dry lint and broad straps of strapping placed around the abdomen, and an ice-bag placed over all. A morphia suppository per rectum. Operation at 2.45; at 3.15 temperature 98·5°. At 5 another suppository; at 10.30 temperature 98·2°.

12th.—9 A.M., temperature 99·4°; 11 P.M., temperature 100·4°.

13th.—11 A.M., temperature 99·2°; 12 P.M., temperature 100·4°.

14th.—11 P.M., temperature 100·2°.

15th.—10.45 P.M., temperature 100·4°.

16th.—10.30 A.M., temperature 98·4°; 9.40 P.M., temperature 100·2°.

17th.—11 A.M., temperature 99°; 10 P.M., temperature 98·5°.

18th.—11 A.M., temperature 98·8°.

19th.—10 A.M., temperature 98·5°; 10.30 P.M., temperature 99°.

20th.—11 A.M., temperature 98·4°; 3 P.M., dressings removed for first time since the operation, and all the sutures removed. The incision is healing by primary union, and looks well. 9 P.M., temperature normal.

23rd.—Temperature 99·1°; evening, 99·6°.

24th.—Temperature 98·5°; evening temperature 100°.

25th.—Morning temperature 98·5°; evening temperature 99·2°.

26th.—Morning temperature 98·5°; evening temperature 98·6°.

The patient has progressed without any bad symptoms, and was discharged on July 16th, "well;" but there is no report after June 26th.

Puncture, penetrating; Wound of Abdomen; Protrusion of Omentum; Recovery. (From notes taken by Mr. Griffiths.)—H. H——, aged twenty-five, was admitted into Accident Ward on Dec. 7th, 1879. The patient was stabbed in the abdomen, and was not aware of the injury until about five minutes afterwards, when he felt a pricking pain, and upon examining himself, found that he was bleeding freely. Soon after the injury he vomited, and vomiting occurred after.

On admission he had an incised transverse wound of the abdomen, about one and a half inches long, and about two and a half inches above the centre of Poupart's ligament, from it a piece of omentum was protruding, and an escape of peritoneal fluid. The omentum was returned after having been well washed with carbolic lotion, and the wound closed with wire sutures, the peritoneum not being included. He was ordered milk diet and one grain of opium twice a day. Eight days later the sutures were removed, the wound having nearly healed. On the 17th he left the hospital, against advice, but apparently well, the reparative process having gone on satisfactorily.

The temperature never rose above normal, indeed on several days it was below the standard.

UNIVERSITY COLLEGE HOSPITAL.

THREE CASES OF TUMOUR OF THE ANTRUM OF HIGHMORE.

(Under the care of Mr. CHRISTOPHER HEATH.)

THE following is the third and last case of the series begun last week:—

CASE 3. *Epithelioma of the Antrum; Pneumonia; Death.*—R. M——, aged fifty-nine, a shoemaker, was admitted on May 30th, 1879. At the beginning of the previous month he had noticed that his right nostril was obstructed; a week or two afterwards the lower lid of the right eye became inflamed, and a swelling which commenced here rapidly extended over the right cheek. About this time a painful swelling of the hard palate appeared, and the patient consulted a dentist, who extracted a tooth. Shortly afterwards he applied at the hospital. His brother was stated to have died of cancer of the kidney. The other members of his family were, so far as he knew, healthy.

He was a pale but well-nourished and well-preserved man for his age, though he had, he stated, lost flesh latterly. Temperature varied from 99° to 100° F. He complained of a feeling of stuffiness in his jaw, but of no pain.

The skin of the right side of the face was reddened, œdematous, and tender, and the cheek was projected outwards by the tumour beneath it. The right eyelids were closed and œdematous, but could be opened slightly, displaying chemosis of the conjunctiva, a clear cornea, and a somewhat sluggish iris. The right nostril was obstructed, and there was a purulent discharge from it; the nasal duct on the right side also appeared to be obstructed, giving rise to overflow of tears. To the touch the tumour gave the idea of a soft solid rather than of fluid. Most of the right half of the hard palate was absorbed, a soft elastic swelling occupying the roof of the mouth, the mucous membrane of the latter being congested and swollen. The teeth of the upper jaw were carious or absent, but the alveolar process was neither displaced nor softened. Owing to the resistance of the patient, an examination of the posterior nares could not be made. The lymphatic glands in the posterior triangle of the neck were enlarged, but free from tenderness. The mouth could not be opened to its full extent, and speech was slightly affected. The tongue was broad, pale, and marked by the teeth.

On the 31st a fine trocar with cannula was inserted into the swelling on the roof of the mouth, and a few drops of stinking pus evacuated. The opening made by the trocar was subsequently enlarged, and a drainage-tube was passed into the antrum.

It soon became evident that the growth was malignant, and as the man's condition became worse daily, removal of the upper jaw offered the only chance of prolonging his life. This was accordingly done on June 4th. The floor of the orbit was taken away, but it was impracticable to wholly extirpate the growth in this direction, as the orbital structures were infiltrated. The somewhat free bleeding was restrained by the actual cautery, and the cavity of the wound was stuffed with strips of lint soaked in a strong solution of chloride of zinc.

The growth appeared to have commenced in the antrum, the walls of the latter being partially absorbed, the anterior almost wholly, thereby allowing invasion of the orbit, the mouth, and the pharynx. Several pieces of dead bone, surrounded by offensive pus and débris of broken-down growth, were found in its cavity, thus accounting for the inflammatory condition of the superjacent skin, and the purulent discharge from the mouth and nostrils. In other parts the growth was of a yellowish colour, translucent, gelatinous, and vascular. Several ordinary soft gelatinous polypi were extracted from the right nostril during the operation.

In sections taken from the margin of the growth near the gum, the microscope showed cylinders of epithelium cells, irregular in form and sinuous in outline, sometimes anastomosing, set in a stroma made up of fibrous tissue and spindle-shaped cells. Epithelium "nests" were observed here and there, but these were few, small, and ill-developed.

Digitized by Google

The papillæ of the mucous membrane covering the gum, where the latter was infiltrated, were hypertrophied. The histological characters of the growth appeared to correspond with those of the "épithéliôme tubulé" of Cornil and Ranvier.

On June 13th pneumonia was present at the base of the right lung, and on the following day friction sounds were audible over the affected area. The edges of the skin wound had united, except at the inner angle of the orbit.

On the 16th there were dulness, extremely weak breath sounds, diminished local fremitus, and resonance to the angle of the right scapula, with bronchial respiration above. The lymphatic glands, which had become larger and very tender in the right posterior triangle, had diminished in size after treatment with belladonna and poulticing.

On the 18th, the physical signs of pneumonia at the left base became evident, and the general condition of the patient worse, though he wanted to "be up and about." The fetor from the cavity of the wound was now almost intolerable, and one or two sloughs had separated.

From this time the chest symptoms increased in severity, and he died on June 26th.

Necropsy (by Mr. BARKER) *twenty-five hours after death.*—Rigor mortis well marked. Body well nourished. The serum in the pericardium was normal in amount and characters. The heart was somewhat enlarged, and rigor mortis was well marked; a good deal of fat was noticed chiefly on the anterior surface. The superficial veins were somewhat loaded. The right auricle contained firm post-mortem clot. The right ventricle was also engorged with clot, part of this having evidently formed during several hours before death. The left ventricle was firmly contracted, and contained a small quantity of tough coagulum. The cardiac valves were healthy. The left lung was extremely emphysematous anteriorly, and posteriorly it was covered with recent lymph, hardly adherent. There were six ounces of serum in the left pleural cavity. The inferior lobe was considerably congested, and some small portions were collapsed. Section showed general congestion and grey hepatisation and softening at numerous points, but the lung was not gangrenous. The bronchi were intensely congested in patches down to the smaller ramifications, and full of dirty brown sero-mucous fluid. The right lung was adherent to a large extent to the ribs, particularly over the lower lobe, and by more recent lymph above. A large abscess opened on removing lower lobe from chest wall. This abscess, occupying a large portion of lower border of upper lobe, upper border of lower lobe, and extending deeply into the substance of the lung, was a ragged, ill-defined space, full of black, very fetid broken-down lung tissue, and was surrounded by blackened, sloughing, very soft lung tissue. The bronchi, as in the left lung, were intensely congested, increasingly so towards the finer ramifications, and full of foul sero-pus. The bronchial glands were much enlarged at root of both lungs. The tongue was covered with a thick covering of foul material, apparently dropping down from the roof of the mouth. There were enlarged papillæ at the base, the size of millet seeds, raised, pedunculated, and deeply pigmented. The œsophagus was normal. The mucous membrane of the larynx and trachea was inflamed throughout. There was a quantity of grey mucus in the ventricles of the larynx. The anterior surface of hard and soft palate was covered with foul, tenacious pus. The operation-cavity extended back beyond orbit to the pterygoid fossa upwards to sphenoid bone. The septum of the nose was carious, and giving way. The orbit and eyeball had not been particularly injured by the operation. The liver was apparently normal. There was no post-mortem staining in the great vessels, nor extravasation in the mucous membranes of the intestines.

LEEDS GENERAL INFIRMARY.

CASES OF NERVOUS DISEASE, PRESENTING OPHTHALMOSCOPIC PHENOMENA.

FOR the notes of this interesting series, concluded from page 447, we are indebted to Dr. E. H. Jacob, late resident physician.

CASE 10. *Multiple Paralysis; Anæsthesia; Optic Neuritis.*—H. J——, aged nineteen, was admitted on April 30th, 1878, under the care of Dr. Heaton. She was married, and had had two children. Her last confinement, four months ago, being easy and natural.

Six weeks ago she found one morning she had lost sensation in the left half of her upper lip. The next day this had extended to the whole cheek. The day after she had some loss of sight in the left eye, and the numbness extended to the forehead and side of the neck. With this her right leg began to be numb, though there was not complete loss of sensation. In a few days the sensation returned to the anæsthetic parts, but there still remained some loss of sight. About a week after this the left leg began to lose sensation, and in four days she had lost all power over it as well; this was followed by a similar affection of the right leg, ending in complete paraplegia. At the beginning of the attack she lost power over her bladder for a week; this returned naturally.

The patient was a bright-looking intelligent girl, but rather pale. She answered questions clearly. There was complete loss of power over both legs, and sensation was so far impaired that she could not feel a light touch anywhere below the umbilicus. Reflex action was increased. There was nothing abnormal in the back. No tenderness or increase of sensibility to heat or cold. She said her legs sometimes burned and jumped. There was complete loss of sight of outer half of the field of vision on the left side. The pupil was dilated and insensible to light; the optic disc was a large, woolly-looking mass, with dilated tortuous vessels partially hidden by effusion. The disc in the right eye was rather white, but apparently healthy. She was ordered brisk, cutaneous faradisation with a metallic brush. The muscles acted to a moderately strong current. A tonic iron mixture was also prescribed.

On May 6th, she could move her toes slightly, and feel a very light touch on both legs. On the 8th, she could move her feet a little, sensibility was perfect. The field o vision was perfect, and there was less effusion on the disc. On the 13th, there was still effusion over the whole fundus, especially the apparent inner half. The disc was woolly but fairly defined. There was a slightly more marked patch of effusion straight above the disc. On the 17th, the disc was much clearer, but there were some streaks of effusion along the vessels. She could walk with assistance, and read large print with the left eye. On June 3rd, she could walk slowly without assistance, the left disc was clear but the vessels were large and tortuous. She could read moderate-sized print, but said the letters looked misty. She was discharged a few days later.

Remarks.—The severe, but transient and variable, nature of the paralysis and anæsthesia in this case removes it from the category of organic disease. Ophthalmoscopic signs, however, though functional amblyopia is common, appear to be very rare in hysterical cases. No case of the kind is mentioned by Dr. Gowers in his "Atlas of Medical Ophthalmoscopy," although he quotes Landolt as having seen dilatation of vessels and serous transudation into the retina, in connexion with extreme amblyopia. Unilateral optic neuritis is a phenomenon of rare occurrence, though two cases have been reported by Dr. Hughlings Jackson, in which the affection was on the opposite side to the cerebral tumour.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Granular Contracted Kidney.—Dilatation of Fallopian Tubes.—Fatty Degeneration of Muscles in Infantile Paralysis and Talipes.—New Method of Mounting.—Cancer of Breast.—Melanosis of Finger.—Epithelioma of Penis.—Aneurism of Mitral Valve.—Disease of Pulmonary Valves.—Ulcer of Stomach.—Drawings of Cancer.

THE ordinary meeting of the Pathological Society was held on Tuesday, the 16th inst., the President in the chair. There was a large attendance of members. A number of specimens illustrating the changes met with in granular contracted kidney were exhibited by Drs. Saundby and Greenfield, and the discussion upon them was the main incident of the evening. At the close of the meeting the President announced that Dr. Hilton Fagge had consented to introduce the discussion on Rickets, which was arranged to commence at the second meeting of the Society in November.

Digitized by Google

Dr. SAUNDBY, before describing his specimens of Chronic Granular Kidney, which were under the microscopes in the adjoining room, referred to the views of Johnson, Traube, and Gull and Sutton, each of which was partly true but also insufficient. He classed the changes into those in the tubes, in the interstitial tissue, and in the vessels. He claimed that his specimens showed the epithelium in the tubes to be actively proliferating, and filling the tubes with free nuclei; in places these nuclei could be seen undergoing transformation into spindle cells, while where the change was more advanced, wide tracts of hyaline connective tissue containing a few spindle and stellate cells were seen. In many places part of a straight tube was seen filled with a delicate granulation tissue which, becoming gelatinous, formed a tiny mucous cyst. It might be thought that this conversion of epithelium into connective tissue was a breach of Remak's embryological law, but as the Wolffian ducts, tubes, and glomeruli are believed to be formed from the mesoblast, we must regard the renal epithelium as genetically connected with the connective tissues. Dr. Hamilton has recently described a similar process in cirrhosis of the liver, Dr. Creighton in the mamma, and it can be demonstrated in the lungs also. Secondly, the capsule and intertubular tissue is widened by swelling, by increased intercellular secretion and growth of its formative elements; but there is an entire absence of any appearance of general nuclear proliferation. The Malpighian capsules are also thickened, the glomeruli atrophy, and the epithelium lining the capsules and covering the vessels proliferates and forms a little mass of granulation tissue which in most cases becomes gelatinous and forms a mucous cyst. Thirdly, the vessels with differentiated coats are greatly dilated, the endothelium proliferates and narrows the lumen, the elastic laminæ are swollen and separated, the muscular coat is swollen and hypertrophied, and the adventitia blends with the hyaline connective tissue around it. The vessels with homogeneous walls are seen to be formed of concentric layers of spindle cells identical with muscular fibres, the walls being of great thickness. These vascular changes are merely those met with in the vessels of inflamed tissues generally; but some amount of the thickening of the vessel-walls probably occurs anterior to the commencement of inflammation. The commencement of the lesion in the parenchyma and the filling of the tubes with nuclei have been often observed and taught. To these views he would add the statement that the nuclei of the proliferated epithelium become converted into spindle cells and connective tissue. A similar fact has been noted elsewhere by Drs. Hamilton and Creighton. The mode of cyst-formation he has described is also, he believes, new in this situation. His views on the much debated question of the vascular changes are those generally held on the Continent.—Dr. GREENFIELD had promised the secretary to exhibit some specimens bearing upon this subject, but had felt a difficulty in doing so, as he was in ignorance of the ground to be traversed by Dr. Saundby. He had hoped that Dr. Saundby would have discussed the pathology as well as the histology of the affection, would have dealt with its etiology, and shown how it interferes with the renal function; but in all this he had been disappointed. There was much doubt about the whole subject; all of the three views mentioned by Dr. Saundby contained parts of the truth, and with improved methods of research it was reasonable to hope for more definite and accurate knowledge. The specimens he exhibited were intended to show what he believed to be the initial and important changes in the kidney; they were the antitheais to Dr. Saundby's. He had been quite unable to trace the development of connective tissue from the epithelium, and having examined a large number of specimens he was of opinion that this change must occur in only a small minority of cases, if at all. Dr. Saundby had not adopted Charcot's view, which was, that interstitial change was often subsequent to epithelial change. He had pointed out that after ligature of the ureter in a guinea-pig great interstitial proliferation was found, while the glomeruli and arteries were free from change, in this respect differing markedly from granular kidney. He suggested that this was subsequent to epithelial proliferation. His own specimens illustrated a condition common to many forms of renal disease, constituting a primary change in all cases of chronic disease, even the lardaceous form. The change in question is a proliferation of the epithelium lining the glomeruli which leads to a formation of connective tissue, compressing and so causing atrophy of the contained capillaries. There is also proliferation of the epithelium covering the glomerulus, and there may be a fusion of this tissue with the lining of the capsule in one fibrous mass, which he thought was the mucous degeneration of Dr. Saundby. There is in addition a thickening of the fibrous capsule of the glomerulus which spreads out around the convoluted tubes. This he believed to be the initial and most important change in chronic renal diseases. If the kineys of people suffering from a general fibroid disease in whom there is morbid renal change are examined, this change in the glomeruli is found in scattered patches. The glomerulus is the apex or extremity of a renal tube, and, with it, may be looked upon as a renal element. It is well known that the greater part of the water of the urine is secreted in the glomerulus; if this then is interfered with the tube below is deprived of its usual stimulus and the epithelium lining it atrophies and dies. And further, the arterial flow being obstructed through the glomerulus the circulation in the vessels beyond—those round the convoluted and straight tubes—is also impaired, causing lessened excretion from them and their ultimate atrophy. This glomerular change is often seen to be limited to certain conical patches of cortex, and to regions surrounding the interlobular arteries. In pure granular contracted kidney the change is essentially atrophic: the tubes waste, the epithelium degenerates and remains as only a few cells. He had found this change in nearly all examples of chronic renal disease. In the form met with after scarlatina it was very constant and might be the only change. One of his specimens was taken from a boy who died from acute dropsy on the forty-ninth day after the onset of scarlatina, and the change was almost limited to the glomeruli. In the large white kidney the change is essentially interstitial, and in the glomeruli all the stages of the change are seen. It is also met with in the last stage of lardaceous disease when from capillary obstruction there is no longer a flow of blood round the convoluted tubes leading to loss of function and atrophy. In certain cases the granular disease is connected with primary change of the arterioles, a thickening of all the coats. The later changes met with in the vessels are those of atheroma, or endarteritis deformans, a thickening of the inner and outer coats. He did not think Dr. Saundby had brought forward a clue to the pathology of granular contracted kidney. He had drawn attention to these glomerular changes because they are not mentioned in the text-books, or hardly at all; they are not the primary change in the large white kidney, and in acute renal disease there is inflammation with exudation and epithelial degeneration. In scarlatinal nephritis he had traced the connexion between the changes in the glomeruli and tubes. In the kidneys of a boy who died from renal disease three months after scarlatina, and which were at first sight quite healthy, he had found at certain parts remarkable proliferation of the cells covering the glomeruli, while in the convoluted tubes prolonged from them the epithelium had lost its granular character, and had become flattened below.—Dr. MAHOMED thought Dr. Saundby had added considerably to our knowledge of this subject, his specimens showed the origin of connective tissue from the epithelium. But he was sure that all granular kidneys had not this origin, and it was a great mistake to speak of this disease as one—there were three distinct forms of it. The first was that in which there is granular kidney without any clinical evidence of it, a part of a general fibroid disease—Sir W. Gull's arterio-capillary fibrosis—where there is a distinct intertubular exudation followed by dense fibrous change. The second was the mottled yellowish granular kidney with tubules full of epithelium undergoing degeneration—a true granular kidney with symptoms during life. These changes largely result from a fibroid degeneration of the epithelium. The form of granular kidney met with in young people shows well marked epithelial change. The third form is the lardaceous granular kidney. Many large white kidneys begin as lardaceous disease, followed by changes in the arteries, and a true nephritis producing the granular form of the disease.—Dr. N. MOORE could not clearly distinguish between Dr. Mahomed's first two forms of the granular disease. He was also anxious to learn whether Dr. Saundby was able to point out the difference between the two classes of granular kidney, which were clinically so distinct; in the one often following scarlatina there were the symptoms usually associated with a large swollen kidney, and death ensued in two or three years, and the kidneys were found to be small, pale, with a thickened capsule; in the other there was a general fibroid change throughout the body. The two kidneys when

Digitized by Google

granular may be indistinguishable, but surely they begin differently.—Dr. MAHOMED explained that arterio-capillary fibrosis is met with in any form of true renal disease; it may occur alone, or in conjunction with kidney disease proper.—Mr. EVE thought that serious objection must be taken to Dr. Saundby's view of the development of connective tissue from the nuclei of epithelial cells; it was entirely contrary to our present knowledge; it was common to see collections of leucocytes round epithelial changes, especially in the breast and tongue.—Dr. HOGGAN thought Dr. Saundby's specimens did not support his statements. What were called small cysts he regarded as tubes bare of epithelium seen in section, while the spindle-shaped cells were the nuclei of the shrivelled and atrophying tubes seen in the same way.—Dr. SAUNDBY reminded Mr. Eve that the kidney was developed from the mesoblast, and that therefore its epithelium had genetic relations with connective tissue. He thought that granular kidneys were subject to intercurrent attacks of inflammation which caused interstitial fatty degeneration, which made the main difference between the different varieties of the disease. He made no pretence whatever to throw light on the etiology of the disease, which he considered quite a distinct subject, and too large to be combined with that he had brought forward, which was simply the histology of the affection. One objection to Dr. Greenfield's view was the fact that the water-secreting function was not early interfered with, as would be the case if the glomeruli were primarily diseased.—Dr. GREENFIELD replied that the increased flow of water was due to the greater lateral pressure in the healthy unaffected glomeruli necessarily resulting from the obstruction in the diseased; while the atrophy of the excreting tubules explains the diminution of the urinary solids. The first form of chronic granular change is probably primarily vascular; the other arises from renal change.

Dr. MULES (Manchester) showed some specimens mounted by a new method introduced by Mr. Priestley Smith, the minor details of which he had slightly altered. They were specimens of various diseases of the eyeball, mounted in glycerine jelly. They were prepared by being hardened in Müller's fluid and then decolorised by chloral, or hardened in alcohol; others were mounted fresh from carbolic glycerine. The specimens shown had been mounted two years, and their colour and appearance were perfectly preserved. In answer to Mr. Doran, Dr. Mules stated that by this method the œdematous appearance of specimens could be preserved.

Mr. NUNN showed drawings and sections of three tumours. The first was a Cancer of the Breast, which was removed from a lady between fifty and sixty years of age, from whom Mr. Curling had removed a tumour seven years before. The recurrence was small, and removed early. Dr. Goodhart had examined the first tumour, and stated that it was a peculiar form of scirrhus: his specimen showed that the recurrent growth retained these peculiar characters, for it consisted of very minute cysts lined by columnar epithelium, and containing a quantity of obsolete blood in the centre. The second was a specimen of Melanosis of the Finger, also from a lady between fifty and sixty years old. For more than a year she had noticed what looked like an ecchymosis on the finger, which was supposed to be due to the pressure of a ring worn on the next finger during a squeeze of the hand. During the last six months it took on a more malignant aspect, and declared itself as melanosis. The melanotic cells are diluted, as it were, with a large number of leucocytes, as if the later growth had been a development of these colourless cells between the older pigmented ones. The third was an Epithelioma of the Penis from a gentleman aged seventy, showing a great development of epithelium.—Mr. GODLEE exhibited before the Society some years ago a tumour closely resembling the cancer of the breast; it had recurred locally, after removal by caustics, and then again in the axilla; it was composed of similar cysts containing blood. Mr. Nunn's case was the only other example he knew of.—Dr. THIN said that the section of the breast tumour under the microscope satisfied him that the tumour was one of the class he had described in a paper he had read before the Medico-Chirurgical Society as duct-cancers. These duct-cancers were essentially the same in structure as the tumours usually called adenomas. In the commoner form, that usually recognised as adenoma, a cluster of small epithelial tubes was the usual appearance; but in some cases, and Mr. Nunn's case seemed to him to be one of them, a further development took place. Instead of the tubes a large mass of cells was formed. These cells broke down in the centre of the mass, leaving a cavity lined with epithelium, and from the walls of the cavity secondary growths sometimes sprouted into the free space. He had been able to examine sections of tumours prepared in various London hospitals and in Edinburgh, and had found transition forms from the commoner adenoma to the rarer forms the growth assumed, of which the present was an example. The cancer of the mamma following disease of the surface of the nipple was in all the instances he had examined of this form, and as in these cases the disease was rapid and fatal, it seemed that the disease, when it took its origin from the epithelium of the larger ducts near the surface of the nipple, was much more severe than when it developed deep in the breast from the smaller ducts. The clinical difference between this form and scirrhous cancer was, he thought, illustrated by the history of Mr. Nunn's case.—Dr. S. MACKENZIE asked how long the finger had been removed, whether there was any recurrence, and whether the blood had been examined at any time. He thought an examination of the blood would be of great service in showing the existence of dissemination of the pigment.—Mr. NUNN replied that there was no secondary deposit and no recurrence; the blood had not been examined. He had some specimens of adenoma of the breast showing a structure just like the prostate gland. His specimen of cancer of the breast was referred to the Morbid Growths Committee.

Dr. N. MOORE showed a specimen of Disease of the Valves of the Pulmonary Artery, which was found in a woman aged thirty-six, who died a week after parturition from right pleuro-pneumonia. The valves were red and swollen, and affected with old and probably also recent endocarditis. He could not find any evidence of pulmonary embolism. Dr. N. Moore also showed a specimen of Ulcer of the Stomach. The patient, a woman aged thirty-four, died from intestinal obstruction due to a band constricting a loop of ileum. For three to four days before death there was uncontrollable vomiting, and after death a small ulcer was found in the stomach, close to the pylorus, and a similar one in the jejunum. He thought the gastric ulcer was the result of the vomiting.

During the evening the following card specimens were exhibited:—

1. Dilatation of Fallopian Tubes, by Mr. Alban Doran.
2. Dissection of Calf of Leg in a case of Infantile Paralysis, showing Fatty Degeneration of Muscles and Nerves, by Mr. Alban Doran.
3. Dissection of Leg in Congenital Talipes Equino-varus, showing Fatty Degeneration of the Muscles, by Mr. Eve.
4. Drawings of Cancer, by Mr. Hulke.
5. Aneurism of Mitral Valve, by Dr. N. Moore.

The meeting then adjourned.

CLINICAL SOCIETY OF LONDON.

Spontaneous Gangrene of Fingers.—Congenital Cystic Hygroma.—Intrathoracic Sarcoma.

THE ordinary meeting of this Society was held on the 19th inst., Dr. E. H. Greenhow, F.R.S., President, in the chair. The subject of Cystic Hygroma, introduced by Mr. T. Smith, led to some interesting remarks; and the question of the differential diagnosis of pleural effusion and new growths was raised on a case of the latter contributed by Dr. de Havilland Hall.

A remarkable case of Cardio-Pulmonary Bruit was shown by Dr. TAYLOR.

Mr. T. SMITH read notes of a case of Spontaneous Gangrene of the Thumb and Fingers of the Right Hand. A fairly nourished girl, three years of age, was admitted into the Hospital for Sick Children, suffering from an abscess in the thigh. The abscess was treated antiseptically. For some time she had suffered from pains in the feet and legs, and her extremities were mostly bluish and cold. Whilst under treatment for the abscess the fingers of the right hand became the seat of an erythematous blush, and no pulse could be felt at the wrist; then blebs formed, and the fingers and thumbs became gangrenous, separating at the metacarpal joints. Mr. Smith expressed himself unable to account

Digitized by Google

for the gangrene. It seemed as if the habitual chilled state of the hands had gone beyond its usual limit, and so led to blood-stasis and gangrene; for in other respects the child's health was good, and there was no evidence of renal or cardiac disease, nor of embolism. The gangrene was limited to the hand.—Dr. SYMES THOMPSON said that five or six years ago he was consulted by a Russian general, who suffered so much from coldness and powerlessness in the feet that he could only walk for five or ten minutes at a time, and then had to sit down. Dr. Thompson could not find a sufficient cause for this; and physicians consulted in St. Petersburg, Vienna, Berlin, and Paris were equally at a loss to account for the condition. Since then the patient has been attacked with gangrene of both lower extremities, from the toes to the ankle. In reply to the President, Dr. Thompson added that the heart was healthy, there were no signs of atheroma, nor did the pulsation in the lower limbs appear diminished.—The PRESIDENT suggested that the condition in Mr. Smith's case was allied to chilblain.—Mr. CROFT asked whether the blood had been examined microscopically. In obscure cases of gangrene some light might be thrown by noting not only the relative proportion of the red and white corpuscles, but the quantity of fibrin in the blood. Gangrene might be due to deranged nerve-supply, to arterial degeneration (as probably in Dr. Thompson's case), or to altered composition of the blood, as apparently in Mr. Smith's case. To such blood condition alone could be explained the occurrence of "white leg" in young women during menstruation. The child was in ill health from its large abscess in the thigh, and that might have increased the tendency to clotting in the vessels, aided by the languid circulation. Were there any septicæmic symptoms?—Mr. GOULD asked whether there was any evidence of carbolic-acid poisoning when the gangrene came on. In a case of amputation at the hip-joint he brought before the Society last year thrombosis occurred, and he attributed it to carbolic-acid poisoning.—Mr. MACNAMARA said that in poisoning by carbolic acid the movements of the white corpuscles are arrested; and it was possible that clot-formation would be started by this action of carbolic acid upon the vitality of the corpuscles.—Mr. SMITH, in reply, said that carboluria did not occur until three weeks after the onset of the gangrene. He had observed carboluria, in many cases, of children under carbolic-acid treatment. His own view was that expressed by the President, that the case was an extreme form of "chilblain." However, the child had no chilblains elsewhere; she was well fed and cheerful, but flabby textured. There were no signs of septicæmia. The blood was not examined. The spleen was palpable, and there was slight rickets.

Mr. T. SMITH also read notes of Two Cases of Cystic Hygroma. In each the growth was of considerable size, extending from the neck into the axillary and subscapular regions—and both were cured by the same process. The first case was that of a female child about three years old, who came under care in September, 1878. The tumour reached from the elbow to the axilla, and across the thorax as far as the sternum. It grew slowly from birth till the age of one and a half years. Four weeks before admission a blow had been inflicted on the swelling; and when admitted it was acutely inflamed, non-fluctuating, and with a firm, shining surface. In three weeks the local inflammation had subsided, and the cysts had become retracted; so that when the child left the hospital five months later only a sort of fibrous thickening remained. The second case was a female child, aged two years and a half, admitted in August, 1878, with a large hygroma of the neck, extending back to the scapular region. It was composed of large cysts, which lodged in the neck and axilla, and were traversed by large veins. Setons were introduced, and on the third day the cyst had begun to be inflamed. Suppuration followed, and the child was very ill for many weeks, but was eventually discharged, after being in hospital for six months, with the tumour consolidated and very much diminished. Through the kindness of Dr. Barlow he was enabled to show a third case. This was a baby six weeks old, with large cysts below the chin on each side of the neck. Mr. Smith said that about five years ago he collected cases of this affection in a paper in St. Bartholomew's Hospital Reports, and he there remarked upon the capricious progress of such cases—how sometimes the growth would diminish in one direction and increase in another. The largest example was the case of a child at the Hospital for Sick Children, where the hygroma was larger than the child itself; it extended from the chin to the pubes, and down one arm. The child lived to eight or nine years, and died from pneumonia and inflammation of the hygroma. In the paper referred to he had advocated the use of setons for want of a better method of exciting inflammation, although it was attended with risk. He had never tried the iodo-glycerine solution, but should think it would be successful in cases of single cysts—cases, however, which it would be easier to cure by other methods. In all cases where he has tried to remove the cysts the wound has healed badly.—Mr. WARRINGTON HAWARD had no doubt that the use of setons was the simplest form of treatment, although attended with risk. Still a considerable number of cases do undergo spontaneous cure. He had lately seen two such cases. In one case the child fell down and struck the tumour; blood was effused, and as it underwent absorption the tumour contracted. The child being out of health, Mr. Haward had advised operation to be deferred, and then this happy accident occurred, and the growth eventually quite disappeared. In another case, of less extensive character, spontaneous cure took place without obvious injury. The child was four years of age, and it was noticed that, as one part of the tumour diminished, other cysts seemed to become rather more tense. He presumed that as in other serous cysts—e.g., hydrocele—inflammation alters the secreting surface; and, as in hydrocele, sometimes a little and sometimes much inflammation was necessary to start absorption. He, therefore, advised that children suffering from these congenital cysts should be observed for a time before having recourse to operation, for here, as in nævus, the larger the growth the more likely was it to get well spontaneously, because of its greater liability to injury.—Mr. GODLEE asked for information upon the pathology of these cysts. He had lately removed some small cysts from a child's arms, the lining membrane of which showed typical lymphatic epithelium. The tumour resembled a fatty growth before removal. The wound healed in three or four days.—Mr. PARKER had seen two or three of these cases. The first was one at Great Ormond-street Hospital, which, at Mr. Smith's suggestion, he treated by the use of setons, and the case did well for a time, but the hygroma refilled three or four months afterwards. Later the child contracted scarlet fever, and after that the hygroma disappeared. He remembered another case at the London Hospital, under the care of Mr. Maunder, who, in removing it, found it had deep connexions with the cervical vertebræ. The growth consisted of connective tissue, with loculi full of fluid. In a third case the cyst, which was a single one, dwindled away after slight inflammation had occurred. He asked whether it was not unusual to meet with them on both sides of the neck.—Mr. HOWARD MARSH said that before Mr. Smith's paper—one of the best essays in children's surgery—was written, but little was known about these cysts. Mr. Cæsar Hawkins, some years ago, had pointed out the great difficulty there was in their removal owing to their deep connexions, for in one case Mr. Hawkins found the growth passing between the œsophagus and the spine. But they were not limited to the neck. Mr. Holmes had a case below the ischium, and in removing it exposed three inches of the rectum. Mr. Marsh himself once saw a child, nine days old, with a cystic tumour of the cheek, preventing closure of the mouth, and sending out lobes which pushed the soft palate on one side. As the growth was enlarging towards the pharynx he made an incision over the tumour, and dissected it out from under the zygoma, taking away also one-half of the soft palate. The child recovered. Sometimes these cysts occurred on the trunk, sometimes on the arms. He agreed with Mr. Haward that in many cases they may be left alone, but in some the growth goes on enlarging, and it is imperative to interfere. The use of setons was dangerous, often attended by severe illness, sometimes with loss of life.—Mr. PARKER added that he had under his care an adult suffering from a similar cystic growth in the neck, which he had injected with Morton's fluid, the injection being followed by much pain in the arm.—Mr. SMITH, in reply, endorsed Mr. Haward's statement that the larger of these cysts were those most prone to get well spontaneously. Still, sometimes interference had to be had recourse to when there was danger from suffocation. Any kind of curative treatment, of course, involved risks. The disease does occur in other parts of the body—e.g., they had one case of cystic hygroma of the kidney at the Hospital for Sick Children. He had seen another case where a child's belly became so distended and round that it looked like a large gooseberry. The child was

Digitized by Google

so well that Mr. Smith postponed operating; and one day the child, after dinner, fell off a high chair and "burst himself." The swelling thenceforth disappeared. No doubt this was a case of this class. He could not say what was the precise pathology of these hygromas, to which Mr. Godlee's case seemed to belong. Cysts separated by tissue like that in the umbilical cord were their gross features. He did not think it very rare to occur on both sides of the neck. Mr. Cæsar Hawkins gives an instance where the disease underwent an apparent spontaneous cure, but at the end of fifteen or twenty years began to grow again.

Dr. DE HAVILLAND HALL read notes of a case of Intrathoracic Sarcoma. The patient, a clerk, aged nineteen, had enjoyed good health until nine weeks before, when he "caught cold" whilst playing cricket, suffered from shortness of breath, and a slight cough, but had no hæmoptysis, nor was there severe pain. In three weeks' time he gave up work, and was treated by a medical man for pleurisy. He was admitted into Westminster Hospital on Dec. 6th, 1879. He lay on the left side; there was absolute dulness on this side in front from the second rib downwards, and behind from the spine of the scapula. Vocal fremitus was diminished, but not quite abolished. The heart's impulse was seen one inch within and below the right nipple. Next day he had dyspnœa, and the dulness extended to the clavicle and across the sternum above. An exploratory puncture with the aspirator resulted only in the passage of some cheesy matter. On Dec. 8th he was again tapped, but only blood obtained. Mr. Gould then made an incision, and found caseous material as far as he could reach; and two or three other aspirations in other places yielding no fluid the wound was dressed antiseptically. The course of the case was marked by attacks of dyspnœa. On the 22nd he was much collapsed. Pulse 102; respiration 40. There was dulness at the right base and tubular breathing. He had an alarming attack of dyspnœa on this day, passed a restless night, became cyanosed, and died on the 23rd. The minimum temperature during illness was 98° to 99°; maximum 99·4° to 101·2°. Quantity of urine passed varied from 10 oz. to 24 oz. per twenty-four hours. Post-mortem examination showed an enormous mass of new growth filling the left side of the chest, in the pleural cavity, depressing the diaphragm, and extending across the middle line. The pericardium was displaced to the right of the mid-sternal line, and was adherent to, and implicated by, the growth. The left lung lay completely collapsed along the spine; the bronchi on the right side were full of secretion, and the lower lobe of the lung contained a recent infarction. Some outlying nodules of new growth lay along the spine, behind the parietal pleura. The upper part of the tumour was pale yellow; central part pulpy and caseous; its lower part firm and white. The splenic capsule was thickened; liver and supra-renals normal. The growth was a round-celled sarcoma. The points of interest in the case were:—1st, Short history of illness, the patient being strong and well enough to play cricket only nine weeks before; 2nd, the physical signs of pleural effusion, with the exception of the slight action of vocal functions, in the bulging of chest and displacement of heart—nor was there any sign of centripetal pressure. 4. The rapid growth of the tumour, for when first seen the impulse of the heart was one inch within the right nipple, and later it shifted to an inch outside that limit. Had the caseous matter removed been examined microscopically, perhaps the true nature of the case would have been at first recognised. The growth probably started from the anterior mediastinum.—Dr. DOUGLAS POWELL said that so far as the physical signs went the case showed no distinction from one of pleural effusion, except in the result of puncture. He believed that when that test is thoroughly tried it is conclusive in diagnosis. For if in making the puncture the needle is found to be grasped by a mass, and still more if portions of that mass are removed by it, there should be no further doubt respecting diagnosis. Generally in these lymphomatous tumours pressure signs are not marked, for they often surround vessels without invading or compressing them until quite at the last, so that the only diagnostic point was the result of puncture.—The PRESIDENT said it was certainly to be regretted that the material removed by the trocar was not submitted to microscopical examination. Still he could not agree with Dr. Powell, that failure to get fluid on exploration rendered the diagnosis certain. In two cases he recalled, where abortive punctures were made; and had he not felt sure of the presence of fluid he might have been led to regard them as cases of solid growth. Punctures should be made in more than one place before finally deciding in favour of tumour. The case seemed to be one of lympho-sarcoma of very rapid growth and degeneration.—Dr. TAYLOR mentioned a case of empyema following pneumonia, when a first puncture failing, a second was made with a larger needle, and resulted in evacuation of the pus.—Dr. POWELL explained that he referred to cases of extensive effusion or extensive solid growth sufficient to cause displacement of the heart. In such cases the result of puncture would settle the diagnosis. Was there any hæmoptysis?—Mr. GOULD said that his impression of the result of aspiration was that the pleura was lined by a thick layer of concrete pus, which blocked the tube, and prevented the escape of fluid.—Dr. HALL, in reply, said that Mr. Butlin had examined the growth, and said that it was a sarcoma and not a lymphoma. The history of the case was unlike that of malignant growth. The lad got wet through when playing cricket, and from that time began to suffer from pain in the chest. Nine weeks afterwards he presented all the signs of a large pleural effusion, which *rapidly* increased. He had never heard of any tumour growing so rapidly as to displace the heart to so great an extent in so short a time, and he therefore had several punctures made. There was no hæmoptysis.

The Society then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

AT the meeting on March 3rd (Dr. Playfair in the chair), Mr. LAWSON TAIT read a paper on Axial Rotation of Ovarian Tumours, leading to their Strangulation and Gangrene; three cases successfully treated by immediate Ovariotomy. The first case of the kind which the author had met with was that of a woman aged forty-eight, on whom he had operated for a femoral hernia, supposed to have been strangulated for two days. The patient died in five days. The autopsy revealed a small ovarian tumour not recognised during life. It was black and gangrenous from twisting of the pedicle. Of the three cases now recorded, the first was that of a woman forty-six years old. In March last the author diagnosed a small monocystic tumour, probably parovarian. On June 9th she returned with the tumour much enlarged, and suffering from intense abdominal pain. Immediate ovariotomy being performed, the author found the cyst of a black-pearly colour, universally adherent by recent lymph. The pedicle was twisted three or four times. The patient made an uninterrupted recovery, though no Listerian precautions were used. The second case was that of a woman aged thirty, who had noticed gradual increase of size for nine months. Sudden and violent pain in the abdomen occurred on Nov. 6th, followed by incessant sickness. Ovariotomy was performed on Nov. 17th, with Listerian precautions. The tumour was dark-purple, friable, and universally adherent by recent adhesions. Bleeding was controlled by the application of solid perchloride of iron. The pedicle was twisted twice. The patient survived, but made anything but an antiseptic recovery. The third case was that of a woman aged thirty-six, who had not menstruated for seventeen weeks, but had noticed an increase of size too rapid for ordinary pregnancy. Intense abdominal pain, followed by sickness, came on on Nov. 11th. Immediate ovariotomy was performed. The uterus was found occupied by a pregnancy of about the fourth month. The tumour was a parovarian cyst of the right side, and was of a pearly-black lustre, and the pedicle was twisted three times. Listerian precautions were used, and the patient made a better recovery than the second case, but not so good as the first. No symptoms of miscarriage appeared. In all these three cases the tumour was one of the right side, and the pedicle was twisted from within outwards and to the right side. From this circumstance the author deduced a theory as to the causation of the rotation—namely, that it is due to the alternate filling and emptying of the rectum. The fæces descending the rectum would act as a wedge, and the point of application of the force would be the most favourable possible in the case of a right-sided tumour.—Mr. KNOWSLEY

Digitized by Google

THORNTON related several cases in which, on performing ovariotomy, he had found the tumour gangrenous from twisting of the pedicle. He agreed with the author that immediate ovariotomy should be performed when symptoms arise leading to a suspicion of such a condition. In some cases, however, the necrosed tumour being excluded from septic influence, remained quiescent for a considerable time.—Mr. SPENCER WELLS thought that it was easy to account for the rotation of the tumour by the patients' changes of position. Moderate degrees of twisting were often found without any gangrene being produced. He had seen two patients who died suddenly from very profuse bleeding within the cyst, without its rupture, the pedicles being found twisted. Last year he had removed by ovariotomy a cyst necrosed from twisting of the pedicle, which had been supposed malignant on account of the pallor of the patient. She recovered perfectly.—Dr. BANTOCK had recently met with two cases in which small tumours were found with twisted pedicles. Both tumours were found adherent, and both patients had been attacked by sudden pain, followed by symptoms of peritonitis. He thought that the twisting produced no symptoms, but that the rupture of a bloodvessel was indicated by an attack of pain.—Dr. HEYWOOD SMITH thought that not only should ovariotomy be performed immediately if strangulation of an ovarian tumour were diagnosed, but that, given an ovarian tumour, this should be done should pain suddenly intervene at all. The same theory as to the cause of rotation as Mr. Lawson Tait's had occurred to himself while the paper was being read.—Mr. ALBAN DORAN said that Mr. Tait's theory with regard to the causes of torsion accorded with his own convictions, grounded on experiments made in the post-mortem room. Whether the torsion was progressive or not would depend on the length and elasticity of the pedicle.—Mr. LAWSON TAIT, in reply, said that he hoped that Mr. Thornton and Mr. Wells would publish their cases, with specific details. The rotation could not be accidental, as held by Mr. Wells, if the great majority of the tumours twisted were right-sided tumours, and the twist in a specific direction.

"A refutation of the account given by Professor C. M. Gardien, of Paris, in 1866, to the effect that the Princess Pauline de Schwartzenburg was delivered of a living fœtus some hours after she was burnt to death," was read by Dr. HAIN, Philadelphia. The author examined the evidence in support of Professor Gardien's account, and concluded that it was absolutely valueless.

HEALTH OF LARGE ENGLISH TOWNS.

ELEVENTH WEEK OF 1880.

THE rate of mortality in our large towns remains low. In twenty of the largest English towns, estimated to contain in the middle of this year seven millions and a half of persons, or nearly one-third of the entire population of England and Wales, 5592 births and 3075 deaths were registered last week. The births exceeded by 407, whereas the deaths were 200 below, the average weekly numbers during 1879. The deaths showed an excess of 5 on the decreasing numbers returned in recent weeks. The annual death-rate in the twenty towns, which had declined from 37·0 to 21·4 per 1000 in the six preceding weeks, was again 21·4 last week. During the past eleven weeks the death-rate in these towns averaged 25·9 per 1000, against 23·4, 25·2, and 27·3 in the corresponding periods of 1877, 1878, and 1879. The lowest death-rates in the twenty towns last week were—10·7 in Brighton, 16·5 in Leicester, 17·4 in Hull, and 17·9 in Wolverhampton. The rates in the other towns ranged upwards to 28·3 in Manchester, 28·5 in Nottingham, 30·6 in Plymouth, and 34·8 in Oldham. Measles continued to prevail in Plymouth, and caused 17 deaths during last week. In Oldham the high rate of mortality was partly due to the prevalence of measles and scarlet fever.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had slowly declined from 638 to 457 in the six preceding weeks, rose again last week to 476; these included 169 from whooping-cough, 113 from scarlet fever, 91 from measles, 30 from diarrhœa, and 30 from fever, mainly enteric. The annual death-rate from these seven diseases averaged 3·3 per 1000 in the twenty towns, and ranged from 0·8 in Portsmouth to 9·9 in Oldham, and 15·3 in Plymouth. Whooping-cough showed the largest proportional fatality in Plymouth, Norwich, Salford, London, and Manchester; scarlet fever in Oldham and Norwich; and measles in Plymouth, Nottingham, Oldham, and Hull. Fever, chiefly enteric, caused 10 deaths in London and 4 in Sheffield. Of the 23 deaths from diphtheria in the twenty towns 18 occurred in London. Small-pox caused 11 deaths in London, but not one in any of the nineteen other large towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which in the two preceding weeks had declined from 185 to 172, were 166 on Saturday last; 23 new cases of small-pox were admitted to these hospitals during last week, against 49 and 39 in the two previous weeks. The Highgate Small-pox Hospital contained 16 patients on Saturday last, one of whom, however, was not suffering from small-pox.

The fatality of lung diseases last week was not increased, although the mean temperature of the air was 5° below that of the preceding week. The deaths referred to diseases of the respiratory organs in London, which had declined from 1557 to 315 in the six preceding weeks, were again 315 last week, and were no less than 145 below the corrected weekly average; 220 resulted from bronchitis, and 65 from pneumonia. The annual death-rate from diseases of this class in London last week was equal to 4·5 per 1000, against 5·5 from the same diseases in Liverpool.

NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—I thank you for publishing my letter in your issue of March 6th, and trust attention may be now drawn to the fact that if promotion from surgeon to staff-surgeon be fixed at twelve years, a wrong will be done to those at present heading the list. I cannot assent to your editorial comment "that promotion can scarcely continue for long at ages so low as at present." I maintain that taking into consideration the presumptive ages of officers on the Inspectorial and Fleet Surgeons lists, it will, if present regulations be maintained, even improve still more; of course, I cannot say what it will become should the Admiralty permit further discoveries on the part of officers about to be retired from age.

One of the proposals for a new scheme is, I understand, to retire Fleet Surgeons at fifty-five years of age, another to give £1 a day retirement at twenty years' service. Both these would probably still further increase the flow of promotion from the junior ranks, but should a period of twelve years' "service" or "in the service" be fixed, the benefit of these retirements will be lost to the surgeons, and you will have them by and by doing the duties now delegated to Staff and Fleet Surgeons. The argument I have heard used as to "uniformity" with the army is, I think, a weak one indeed—our lives, our prospects, our everything being so widely different, that the greatest hardship of the army medical officer is his having to take a sea trip in going to or returning from foreign service. Compare the life of the surgeon of a gunboat in the Persian Gulf, on the east coast of Africa, with that of his contemporary serving in the army in India, who is the better paid, who has the most comfortable life?

You say foreign service in a junior rank is sometimes a grievance—certainly, but only when you are required to do what should be another man's turn. It is, as I remarked in my former letter, manifestly unfair that some should be allowed to serve almost continuously at home.

As you mention "meritorious service," I would draw your attention to the fact that every promotion so made under present regulations inflicts a wrong on those over whose heads the "meritorious" man passes; and I think it might be fairly demanded that such promotions, in whatever grade, should be supernumerary until absorbed in due course.

To do justice all round, to endeavour to make the naval medical service a trifle more attractive, will, I trust, be the aim of the committee now appointed to consider the question; to do so they have to keep us *ahead* of the Army Medical Department in *fixed* pay and in promotion. While I hope this may be effected by the new scheme, I am anxious at the same time that no wrong should be done those at the top of the list who have borne the heat and burden of the day.

I am, Sir, yours faithfully,

March 9th, 1880. SURGEON R.N.

THE LANCET.

LONDON: SATURDAY, MARCH 27, 1880.

THERE are few medical teachers in the universities of Scotland who better represent all that is good in their system of teaching than Professor STRUTHERS of Aberdeen, and Professor GAIRDNER of Glasgow. They are specimens of men of good powers and high tone who have chosen to devote their energies to teaching. It is not too much to say that their respective universities owe to each of them a debt of gratitude for the great increase in their prosperity of late years, and for the enhanced reputation of their medical degrees. It is inevitable, therefore, that we should feel a great interest in the evidence which two such teachers have to give on the great questions of medical reform which were being investigated before the abrupt and unexpected dissolution of Parliament, and which will claim attention from the new Parliament.

To take these witnesses in the order in which they were examined, we begin with Dr. STRUTHERS. Dr. STRUTHERS speaks with natural satisfaction of the education and examinations of the Scotch universities in general, and of that of Aberdeen in particular; and it is not disputed that their education is very good, and their system of examinations very efficient. There is, indeed, little to criticise in Professor STRUTHERS' evidence as regards the universities. Is it quite correct to say that they give no half qualifications? Do they not give a Bachelorship of Medicine, apart from a Mastership in Surgery? At the very least do they not charge separate fees for these degrees? Dr. STRUTHERS approves of the suggestion of the Duke of BUCCLEUCH that Conjoint Board examiners might sit together with University examiners. This concession seems to contain the germ of a settlement of the difficulty as regards the universities. But Professor STRUTHERS goes out of his way to extol the examinations of the Scotch corporations. He believed the Scotch corporations had a very good minimum standard, and he believed that if the London corporations and the English College of Surgeons would combine as the Scotch corporations had done that would be all that is necessary! What a delightful solution of a difficult problem, to find the perfection of a minimum examination in the Scotch corporations, and to call upon all other corporations to imitate. Now the world may all be wrong, and Dr. STRUTHERS may be right. But he is not with the majority of people who have pondered seriously on the defects of our examining system in thinking that the Scotch corporations are models of a minimum examination. It is almost amusing to see a Scotch witness give such a turn to his evidence as to give prominence "to the weak points of London and English schools," only to be remedied by turning them into institutions like Scotch universities, and indicating that all that the most earnest reformers should work for is to get the English and Irish corporations to imitate the Scotch ones. It is time to be outspoken in this matter, and to remind Dr. STRUTHERS of what he must well know, that there is an extensive impression abroad that the examinations of the Scotch corporations, if made to include more subjects, are less stringent than those of England in regard to the most vital subjects. This may be a wrong impression, but it is so extensively held that the best friends of the Scotch corporations are those who advise them to demand a system which will secure, as far as any system can, that they shall be placed beyond the risk of comparisons which are disparaging,—not those who speak of their joint boards as models to be copied. Dr. STRUTHERS says there is not a better joint examination anywhere than in Edinburgh. But this, though seeming to imply much, means nothing; for there is not, as far as we know, in any other division of the kingdom, a joint examination at all. Dr. STRUTHERS is rather weak on the subject of the Direct Representation. He is not against it, indeed; and yet he is not for it. He used to approve of it; but "when he saw a man like Sir JAMES PAGET coming forward in the face of ten thousand practitioners he was greatly impressed": his opinion had partly changed. It is as if Dr. STRUTHERS were all sound on the subject till he saw a sort of apparition—"a man like Sir JAMES PAGET"! Sir JAMES will feel flattered that a man like Dr. STRUTHERS thinks more of him than of ten thousand of his professional brethren. We expect the next change of opinion on the part of Dr. STRUTHERS will be in favour of conjoint boards, when they have among their advocates "a man like Sir JAMES PAGET." Moreover, we expect to recover him as an advocate of direct representation when we remind him that Sir JAMES PAGET is not opposed to direct representation. Rather is he in favour of it, as are five out of the eight members of the Medical Council so far examined. Their objection applies only to popular election.

Professor GAIRDNER, in his examination, expressed the opinion, which has so often been refuted, that a Conjoint Board would greatly deteriorate the efficiency of all the universities of Scotland. We will not go over ground which we have so often traversed. We would rather leave it to Dr. GAIRDNER'S own mind to satisfy itself that a movement for raising the minimum examinations cannot depress higher ones. To raise the base of a pyramid is to secure the raising of the whole structure. It is so with minimum and university examinations. Universities would feel compelled, for very honour's sake, to be far above the minimum standard. He objected especially to that part of the Medical Bills which enacted that students can only be affiliated with corporations in that part of the country in which they had passed the Conjoint Board. Dr. GAIRDNER says that his objection would be greatly lessened if this limitation were removed. Clearly it ought to be removed. The examinations should be so equal in every respect—their equality should be so guaranteed—that the student should be entitled to claim affiliation with any corporations he preferred, provided the corporations are to remain the licensing bodies. We are glad that in both Dr. STRUTHERS' and Dr. GAIRDNER'S evidence prominence was given to the unreasonableness of high fees being exacted from the student for the support of numerous corporations, though only receiving one diploma. This comes of having so many corporations to be maintained. We are not sure that Professor GAIRDNER, if more closely cross-examined, would not have

Digitized by Google

come out as a very good medical reformer. He confessed his inclination to a *Staats Examen* similar to that of Germany—like us, not seeing the force of Professor TURNER'S and Professor STRUTHERS' objections to that system, or some modification of it, for this country. There is one expression which Dr. GAIRDNER used which, we think, he would be willing to amend. He thought every practitioner should have a double qualification. Why a *double* one? He should have a complete one after a complete examination embracing all necessary subjects; but a double one implies a division in the knowledge of a general practitioner into halves, medical and surgical, which is now artificial and inconvenient, and ought to be obsolete. Dr. GAIRDNER boasts that all the bodies give a complete examination; what more reasonable than that this should carry a complete diploma?

Finally, there is nothing in either Dr. STRUTHERS' or Dr. GAIRDNER'S evidence to show us that the demands of medical reformers will abate in the least the demand for the degrees and the education of the Scotch universities.

THE *Gazette* of the 16th inst. contains a series of General Orders issued by the Local Government Board, under date the 8th of the present month, concerning the appointments of medical officers of health and inspectors of nuisances, whose salaries are partly repaid by moneys voted by Parliament, in substitution for the Orders which were issued soon after the passing of the Public Health Act, 1872. The new Orders appear to have been called for partly to adapt the phraseology to the Public Health Act, 1875, and partly to effect certain amendments in their details. Moreover, two additional General Orders have been issued applying to the qualifications and duties of medical officers of health of urban and rural sanitary districts, no portion of whose salaries is paid out of moneys voted by Parliament, the qualifications and duties of these officers having been previously left without regulation by the central authority.

As to the Orders relating to medical officers of health who are partly paid out of Imperial funds, and are more directly under the supervision of the Local Government Board, the changes in them appear for the most part to be verbal, in order to meet the altered form of the law since the Orders of 1872 were drafted, but a few touch matters of considerable importance. The reference in the preamble and other parts of the earlier Orders relating to the appointment of medical officers of health to two or more districts is omitted, for what reason does not yet appear, and the possibility of their being appointed to more than one district is noted only of the medical officers of health of rural sanitary districts, and that in relation to their appointed duties. Is the Local Government Board contemplating dealing with the appointment of medical officers of health for two or more sanitary districts in a more comprehensive fashion than hitherto? Let us hope so. In respect to tenure of office the clause limiting first appointments to five years is omitted, and with the omission we trust that the Local Government Board may see a way to sanctioning appointments for a longer period than it has yet done, or even for a permanency. Not that the expunged clause seemed to the uninitiated to forbid this course before in the case of reappointments, but we are given to understand (not daring to express an opinion ourselves on so abstruse a subject) that it did form a bar to the Local Government Board acceding to the wishes of local authorities that their medical officers of health should be permanently appointed. We note, in passing, an addition to the clauses as to the salary, which directs that it shall be considered as accruing from day to day.

The changes made in the section of the Orders relating to the duties of medical officers of health are few, but of considerable moment. The sentence of the earlier Orders adapting them to the case of so-called combined districts, is omitted in the Order as to the medical officer of health of an urban sanitary district, but retained, as already mentioned, in the Order as to the medical officer of health of a rural sanitary district. In Clause 6, which in the earlier Orders directed the medical officer of health, on receiving information of the outbreak of any contagious, infectious, or epidemic disease of a dangerous character within his district, to visit the spot without delay, and inquire into the circumstances of such outbreak, and to advise the person competent to act as to the measures which may appear to him to be required to prevent the extension, &c., the words have been added "after such outbreak," "and in case he is not satisfied that all due precautions are being taken," to do so and so. This addition will relieve many medical officers of health from an unpleasant difficulty they have not unfrequently been placed in by the imperative wording of the clause in the earlier Orders. They have felt that no discretion was left to them in the matter to which it relates when they have been informed of infectious disease in families possessed of every means and of competent advisers for dealing with it without prejudice to the public. We are aware of cases where a medical officer of health has, by reason of this regulation as it formerly stood, been placed in circumstances of considerable difficulty and unpleasantness between his sanitary authority on the one hand and well-to-do families and his professional brethren on the other. The words added to the clause would appear to remove all objection to it on that score. The next clause as to duties (7) supplies an omission to which very much of the imperfection observed in the carrying out of the public-health law is due. The earlier Orders dealt with the inspector of nuisances as having only certain incidental relations with the medical officer of health, and not as part of an organisation in which the medical officer of health must be the co-ordinator, if it were to be worked with any intelligent regard to the object for which it was designed. The present Orders provide that, subject to the instructions of the Sanitary Authority, the medical officer of health "shall direct or superintend the work of the inspector of nuisances in the way and to the extent that the Sanitary Authority shall approve." This would be sufficient to remedy the evil we have referred to, and to place the inspector of nuisances in proper relationship with the medical officer of health, if we could depend upon the advice tendered by the general (lay) inspectors of the Local Government Board—the inspectors who will be concerned in the matter—to sanitary authorities as to the *extent* to which the inspector of nuisances' work shall be directed or supervised by the medical officer of health. It cannot but be remembered that it was owing to the advice of these inspectors the apparent antagonism between the duties of

Digitized by Google

the medical officer of health and the duties of the inspector of nuisances shown in the earlier Orders, and too frequently in practice converted into an actual antagonism, was originally set up, to the immeasurable detriment of public-health administration. However, now that the Local Government Board has seen the defect in its earlier Orders, and removed it, in a fashion, from the present Orders, we must hope that it will be enabled to succeed in obtaining and securing a reasonable interpretation of the clause as it now stands, and that its obvious intention shall not be frustrated by vagaries of its subordinates. The important addition of "milk," which had been omitted from Clause 9 in the earlier Orders, has been made to the articles of foods which a sanitary authority may cause to be inspected and, if they deem necessary, seized. In Clause 14, the directions as to the contents of a medical officer of health's report have been rearranged, and Clause 15 no longer requires that he shall make quarterly reports to the Local Government Board.

The duties imposed upon medical officers of health of urban and rural districts, no part of whose salaries are paid out of imperial funds, are the same as those of medical officers of health whose salaries are in part so paid, with the exception that he is required himself, within seven days of his appointment, to report the same in writing to the Local Government Board.

The new Orders relating to Inspectors of Nuisances are substantially the same as the earlier Orders.

IT is one of the penalties of education by experience that we learn to recognise facts before we are able to define them, but without doubt this is the natural mode of gathering knowledge. The child becomes acquainted with the leading characteristics of fire by almost blinding his eyes as he tries to stare at it, and burning his fingers when he attempts to grasp it, long before he is able to describe or even name the element. Practical knowledge is always in advance of philosophic information with regard to the common things of life, and the majority of veritable and lasting discoveries are made by practical men. It should, therefore, occasion no one any surprise to find that many of the most familiar facts in science and subjects of daily observation are undefined and seemingly undefinable. Every medical practitioner and ordinarily intelligent layman *knows* what is meant by insanity, but as yet no expert or general observer has been found able to frame a definition of the abnormal state which shall cover the disease without including some of the phenomena of healthy life by which the so-called "symptoms" of mental derangement are apt to be simulated. There will be a red-letter day in the chronicles of legal medicine, and a new era in lunacy practice will be inaugurated, when, if ever, a satisfactory definition of insanity is accomplished. We are not about to attempt the feat. It would need to be more than a triumph in technicology.

As the matter now stands, probably no member of the profession would be prepared to admit that he could fail to recognise a "lunatic" or "person of unsound mind," if one were submitted to his judgment; it is, however, impossible to feel sure, except in regard to the most strongly-marked cases, that the opinion one practitioner forms will coincide with that pronounced by another equally trustworthy examiner. Still less easy is it to determine whether the view which may afterwards be taken by a judge and jury looking back on a case of alleged insanity, will ratify the opinion formed by the medical practitioner at the outset on his personal responsibility, and condone such measures as he may have deemed necessary for safety. Much of the delay and no small share of the disappointment attending the treatment of the insane, may be directly traced to the want of a common understanding as to the characteristics of insanity, at least such an understanding as would prevent subsequent dispute as to the very existence of the disease.

The position occupied by the medical man consulted in a case of lunacy is at the present moment both peculiar and painful; it wholly cripples his action, and must effectually, while it is forced upon him, hamper the progress of clinical science and postpone the discovery of improved methods of treatment. In the case of no other class of patients is the medical adviser so strangely placed. It is not enough that a sick person is brought to him for instant judgment, he is confronted at the outset with the danger of a legal penalty in the event of failure to recognise that he is, perhaps, being hoodwinked by the friends, or misled by the fancies, of his patient. While the risks run by other professional men chiefly concern the skill and fidelity of their work as a whole, the practitioner called in to certify in a case of alleged or supposed insanity is placed in jeopardy by his first expressed opinion as to the nature and needs of the patient; and possibly he has had no special training in diagnosis. He is required to assure himself of the good faith of the persons who apply to him, and to form a final and irrevocable judgment as to the verity of such indications as are presented by the alleged lunatic *before* he can safely treat the case.

No one who has not had considerable experience in the early and instant diagnosis of mental disease can have any notion how difficult and embarrassing this task really is. The worst, because the most dangerous, cases are often the least well marked, and a mistake on the side of what seems to be "humanity" is often especially easy where it must be most disastrous. It would be no light task to make a hasty diagnosis in cases of the class we are now indicating, if nothing more than the professional repute of the practitioner were staked in the balance, but he is handicapped with the dread of penal consequences if he errs. On either side perils beset him. If he places a sane man under treatment, he may be cast in a suit for damages. If, on the other hand, he permits a lunatic to go at large terrible events may ensue, for which he will be held morally if not legally responsible. It is easy for lawyers and jurymen to look back on the history of a case of this character, and point to errors of judgment committed by a medical man so placed, but justice requires that the difficulties shall be recognised, and full weight given to the embarrassing nature of the act the practitioner is required to perform under pressure, and amid untoward circumstances, before his conduct is condemned or even severely criticised.

All the difficulty and inconvenience arises from the mistaken policy of confounding functions and responsibilities

Digitized by Google

which are wholly distinct, and, as we believe, incapable of being adequately discharged by the same authority. Why not let the legal questions involved in a recognition of insanity be settled by some official agency, leaving the medical practitioner to study and treat his case in peace, as a professional clinician and therapeutist? If a man has a fit of apoplexy or epilepsy, or fever with active mental excitement, or even the furious delirium excited by drink, the law does not interpose a formal and embarrassing process of certification, with socio-legal aims, between the medical attendant and his task. He can at once set to work to treat his patient, taking all such measures, including coercion, as may be necessary to effect a cure. Considerations of disability for the duties and privileges of health are left to the patient and his lawyers. It would be perfectly easy to place mental disease on the same footing as bodily disease in these respects. At the outset of an attack of "insanity" there is seldom any real difficulty in determining what sort of treatment it requires. The difficulty, where there is any, arises later; just as there might be difficulty, if a medical man were called in after the subsidence of the first symptoms of an acute disease, in determining whether the patient was really ill or malingering.

One of the immediate advantages of separating the civil or legal questions arising in connexion with a case of insanity from the purely medical would be, that the chief motive for concealing the existence of mind disease would be extinguished. We should not then, as now, be perplexed with the delicacy of deciding whether an eccentric person is insane enough to require "certificates," or may be treated at home, or in the family of a medical practitioner, without contracting that "stigma" of lunacy which the friends of the "nervous" so greatly dread and deprecate.

It is surely impossible that the obvious course in regard to this matter of "certifying" will be indefinitely refused. No reform of the Lunacy Laws can be effectual which does not deal with the subject of certifying; and it is not easy to see how it can be dealt with, except by separating it from "treatment" and placing it on a legal footing. Undoubtedly medical knowledge is indispensable on the part of the person giving a certificate, but we are convinced that he should be an *official* appointed by public authority, and not a practitioner—engaged in the discharge of ordinary professional duties—however distinguished or expert. The need of Medicine as a science is to put an end to the severance of "mental disease" from general pathology. Whatever the relations of mind and matter may be, we cannot afford to forego the light thrown on ordinary disease by mind-symptoms; and we do not think "mental medicine" has gained anything, or been rendered more valuable to humanity, by being studied and practised as a specialty. The first step to retrieve errors and amend the situation is to eliminate the *legal* element from what is really a *medical* question—namely, the diagnosis and treatment of insanity. This is necessary before we can hope to find a satisfactory answer to the question—In what does insanity consist?

M. DUMONTPALLIER described, at a recent meeting of the Académie de Médecine, an apparatus for the purpose of lowering the temperature of the body, continuously or intermittingly, the effect of which can be exactly measured. The apparatus consists of two parts. First, a refrigerating envelope, for the purpose of applying to all parts of the body a layer of running water of a fixed temperature. The envelope can be reduced to the required dimensions to encircle the regions of the thorax or abdomen. It is composed of two pieces of silk, so sewn together that a tube of india-rubber, forty metres long and one centimetre in diameter, passes through the parallel spaces left between the stitches. This envelopes the body from the axilla to the groins, and the current of water is never interrupted, whatever be the weight or movement of the body. Moreover, a little apparatus, introduced into the course of the tubes, indicates the least alteration in the flow. The second part of the apparatus, the "distributor," consists of "robinets" placed at each extremity of the tube, which permit the regulation of the flow of liquid, and thermometers adjacent show, at all times, the temperature of the water flowing into and out of the india-rubber tube. The apparatus is supplied by a syphon placed in a reservoir, one metre and a half above the patient. In the use of the apparatus, the axillary and rectal temperature having been noted, the patient is enveloped in the refrigerator, placed in the bed, and covered with the bedclothes. The taps are then opened, and the water quickly circulates through the whole length of the tube. The circulation of the water is so rapid that at first the two thermometers, at entrance and exit, show nearly the same temperature; soon, however, that at the exit rises, in consequence of the abstraction of heat from the body by the flowing water. Then this thermometer gradually falls, because the heat of the body is insufficient to maintain the temperature of water which circulates at the rate of nearly two litres a minute. In from fifteen to twenty-five minutes the thermometer of exit falls 11° or 12° C., and every ten minutes the axillary or rectal temperature will be found to have fallen one or two tenths of a degree; and after an hour, or an hour and a half, the fall of temperature is from 1° to 2° C. Then, if the stopcocks are closed, the thermometers rise equally and progressively, although the rectal or axillary temperature remains stationary for from fifteen to twenty minutes. Sometimes the rectal temperature continues to fall for half an hour or an hour, while the axillary temperature remains stationary or exhibits a tendency to rise. Apparently, in this case, the surface of the body withdraws the heat from the internal parts. Thus, by such an apparatus, the patient remaining in bed, the temperature can be lowered at will during any period and the effect observed.

M. DUMONTPALLIER has studied carefully the effect of partial and total refrigeration of the surface, and concludes that when it is limited to the hairy scalp, to the occipito-spinal region, or to the anterior abdominal or hepatic region, it has little or no influence on the general temperature of the body. The refrigeration of the entire surface of trunk and limbs permits the temperature to be lowered one or two degrees in an hour or an hour and a half. But the refrigeration of the surfaces of the thorax and abdomen by means of the envelope will lower the temperature to the same extent. Ignorance of all that is done outside France is a characteristic of modern French workers. An apparatus essentially the same as that of M. DUMONTPALLIER has for some time been

Digitized by Google

employed by LIEBERMEISTER, and will be found figured in the article on "Abdominal Typhus," in the first part of EULENBERG'S Cyclopædia, now in course of issue.

Annotations.

"Ne quid nimis."

KING'S COLLEGE, LONDON.

THE position held by King's College in the educational world is somewhat anomalous. Those whose memories carry them back to the time of its foundation know how it originated. They recall the sectarian spirit that animated its founders, zealous for the cause of religion, and fearful of the dangers which threatened society by the establishment of the college in Gower-street on a purely unsectarian principle. Meanwhile the world has been growing wiser. The fears have proved to be groundless, and even in Oxford and Cambridge admission can now be had to all but a few of the colleges, free from any subjection to religious tests. King's College, London, however, still retains its tests, claims to act up to the letter of its charter; and yet somehow or other draws to it students and teachers who would probably dispute that they are held under any bondage whatever in the matter of religious opinion. It cannot be that King's College wishes to remain shackled in its selection by reasons which place it on a sectarian basis, for to admit individuals to its secular offices only through the portal of orthodoxy in religion would so narrow its field as to do more harm than good to the institution. The tendency of the day is towards absolute freedom in religious opinion, and to respect the motives of every man who ventures to differ (be it widely or slightly) from so-called orthodox belief. To insist on a rigid conformity to particular doctrines is to uphold the system of tests which one would have thought Englishmen had now recognised to be unjust, if not immoral.

THE FORCE OF PURPOSE.

THERE is no physiological reason to suppose that mental purpose augments the force available for physical activity, but it certainly calls a larger amount of the reserve stock of potential energy into operation, while it concentrates the powers of the system on the particular end in view. How else are we to account for the familiar fact that under pressure of circumstances, or at the bidding of motives that incite to feats of unwonted exertion and endurance, persons of no extraordinary physique are enabled to perform seemingly impossible achievements? Sometimes the energy of an enterprise may, as it were, overpower the agency by which it should be effected, and the result is a break-down in the crisis of accomplishment. As a rule however, happily, determination will carry a man through undertakings which seem so vast as to threaten to overwhelm him. Possibly at no time are the "possibilities" of personal work of a nature which combines activity of both mind and body more conspicuously illustrated than during a "general election." And few events of the class have called out more latent vigour than the time through which we are now passing. From the stupendous exertions of Mr. Gladstone in Scotland to the sleepless energy of some of the candidates and their agents in large constituencies like those of the metropolis, the process of "calling up the reserves" of psycho-physical force is proceeding at a pace and to an extent rarely equalled. Presently the crisis will be passed, and then the exhaustion will begin to declare itself. Those will be wise who recognise what it is they are doing. The stock of force on which they are drawing is not increased to meet the occasion. They are simply using up in an emergency what nature has designed to be held in reserve like the residual air in the lungs, or the volume of atmosphere in the wind-cushion of a set of bag-pipes. If this reserve be exhausted there will be no resilience, and nothing left to play upon. The illustration is inadequate, but it will suffice to point out our meaning. The fact that a great effort *can* be made must not be assumed to show that such an outcome of force is natural. While the feat is in progress, a serious break-down may occur at any moment, and the power of recuperation will in that case be found to be itself exhausted. When the special exertion is over, the fatigue that follows will be more than common weariness. It will be a "dead-point" in the progress of vitality at which special measures of help and recovery are sure to be necessary.

SCURVY AND THE PROPOSED ARCTIC EXPEDITION.

LAST week we published a letter from Commander Cheyne, R.N., complaining of a criticism of ours based on remarks made by him on the question of the outbreak of scurvy in the last Arctic expedition under Sir G. Nares. As there is some discrepancy between what Commander Cheyne says he stated in his speech at the Mansion House and the report of that speech as it appeared in *The Times* of the day subsequent to its delivery, we place both before our readers. In his letter to us, Commander Cheyne states what he said at the Mansion House was "that the seeds of scurvy were in the constitutions of the men of the last expedition before they started on their spring sledging work." Had this been all he said, it would have called for no comment from us; but *The Times* reports Commander Cheyne to have said—"The last expedition came back broken down with scurvy, and the reason was *not the want of lime-juice*, but the want of proper ventilation between decks on board ship, and the want of fresh air and exercise." This statement, made in the face of the evidence obtained by the commissioners appointed to inquire into the outbreak of scurvy among the members of the sledging parties of the late Arctic expedition, gave us reason to fear that Commander Cheyne was disposed to pay more regard to mere hygienic arrangements for the preventing of scurvy than to trust to its absolute prevention by the use of lime-juice; and this opinion was strengthened, because we could not find in any part of his reported speech that he made reference to the antiscorbutic value of lime-juice, but chiefly that he placed reliance on improved ventilation to prevent an outbreak of the disease. It is satisfactory to find that our article has drawn from Commander Cheyne a full confession of faith with regard to lime-juice—a confession that was certainly required after a perusal of his speech at the Mansion House.

THE HISTOGENY OF GRANULAR KIDNEY.

IN his recent communication to the Pathological Society Dr. Saundby opened up new ground in a well-worn, but still disturbed field. Years ago, Dr. George Johnson asserted that the granular kidney was the result of changes mainly limited to the epithelial lining of the urinary tubules. He created the phrase, "desquamative nephritis," and held that the relics of degenerate and atrophied tubules formed the mass of the contracting tissue. Since then the tendency has been to relegate to the tubules a passive part in the process, and to establish the view that the change is mainly that of intertubular new formation precedent to the tubular atrophy. Dr. Saundby showed specimens to prove that there was room for a third view, and that the apparently startling one, that the newly-developed connective tissue was formed from the proliferation of the epithelial nuclei. The

strangeness of the fact was lessened by the consideration that the kidneys are mesoblastic in origin—an argument, by the way, that could not apply to the alleged similar derivation of connective tissue from the hepatic and mammary epithelium. Dr. Greenfield confessed that he had not been able to trace the development of connective tissue from the renal epithelium, but very forcibly and suggestively urged that in the glomeruli were to be found the primary lesions upon which tubular atrophy and other changes followed. His remarks travelled over a wider range than the single point raised by Dr. Saundby; for he added that there was less evidence of intertubular change in the granular kidney than in the large white kidney, thereby, indeed, reversing much generally-accepted opinion, and making it seem as if the terms "parenchymatous" and "interstitial" as applied to these two forms of Bright's disease have been misplaced. It would be impossible, however, to do justice to either observer without far more careful scrutiny of the subject than can here be given to it. It is obvious, however, that much scope is opened up for further careful research in the minute anatomy and the pathology of the various forms of nephritis and renal degeneration. Especially should attention be paid to the slighter and less advanced cases of "granular kidney," if correct inferences upon its histogeny are to be arrived at. To do this thoroughly would require the resources of a pathological laboratory and workers willing to devote their whole time to this investigation. The same indeed might be said of almost every branch of pathology—so multitudinous are its unsettled questions, or rather, its questions which have been only partially settled by being viewed in too limited a manner.

WHAT IS FOOD?

IT seems easy to say that food is what we eat and drink and the body lives upon. By an extension of the formula it may be contended that the mind, too, feeds, and what maintains its strength and gives it energy is also food—"food for the mind," as the phrase goes. Meanwhile we are no nearer a direct and full answer to the question, What is food? That there are limits to the class of materials which may be designated "food" is obvious, because what is one man's food is another's poison. This brings us, practically at least, somewhat nearer the point we want to reach. It may be affirmed generally that, owing to differences of need, and of method, in the maintenance of life in the composite organism of mankind it must be vain to anticipate the discovery of a universally useful dietary. Not only will the food of man always vary with the conditions of his daily life, but with the peculiarities of his individual temperament. A consideration of great moment, which would seem to be too commonly disregarded, is the need of something more than mere digestibility—that is solubility—of the articles offered to the body for its sustenance. It is neither sound policy, nor practicable, to leave what may be termed the organic appetites of the body out of the calculation in arranging for the supply of "food." Just as there is such a thing as somatic life, and another such thing as interstitial or organic life—that is, the life, or lives, of the component parts of the body—so there may be organic appetites and predilections, as well as the gross tastes and likings and dislikings of the individual. We can conceive of a point at which the subtle refinements of skill in adapting "food" to the physiological requirements of the body may break down. Food may be not only too much concentrated, but too little palatable, if we may so say, to the stomach itself, or the organism, to be acceptable. The body is not wholly nourished by physico-chemical processes, such as those of endosmosis and the intermixture of fluids and gases, or the mutual reaction of substances with what re called "chemical" properties. The researches of recent scientists go to show that even the minor constituent parts of the organism have their independent characteristics, and they may also have their individual predilections. In practice we find that many well-intentioned and docile patients *cannot* take what is "good for them," perversely wax fat when they ought to grow lean, or in some other way falsify the prognostications of the empiricist. Setting aside the question whether these idiosyncrasies are natural or acquired, true or corrupt as indications for the kind of food to feed upon, we venture to think they should have great weight; and however excellent and ingenious some of the new schemes of nutrition and special devices for fattening or thinning the body may be, human nature, as we find it, will have to bow to them.

PHYSIOLOGICAL PROPERTIES OF EMETIN.

A PHYSICIAN in Dorpat, v. Podwyssotzki, has recently published in the *Archiv für Experimentelle Pathologie* the results of his observations on the effect of pure emetin. He states that the emetin usually sold contains tannic acid and colouring matter. When purified from these foreign substances it was found to be soluble in alcohol, ether, bisulphide of carbon, chloroform, and all ethereal and fat oils, but soluble with difficulty in cold water, benzin, and petroleum ether. It melted at 62° to 65° C. (144° to 149° F.) It tastes rather sharp and bitter, as do also its combinations with acid. If kept in the dark it remains white, but assumes a yellowish hue when exposed to the sunlight. It crystallises out of concentrated solution of petroleum-ether or benzin in needles, and when treated with concentrated nitric acid it yields oxalic acid. The subcutaneous injection of 0·005 to 0·01 gramme in frogs caused gradually developing paralysis and loss of reflex excitability. The irritability of the muscles, however, remained unaltered both with direct and indirect stimulation with induction currents. Frogs recovered completely from the paralysing influence of the smaller of the above doses in the course of twenty-four hours, whilst the larger doses proved fatal. Injections made into the exposed hearts of frogs caused, after a short period, various irregularities, the ventricle contracting peristaltically, its force diminishing, and its frequency being less than that of the auricle. Ultimately the whole heart passed into a condition of perfect relaxation or diastole, which could not be removed either by mechanical stimuli or by atropine. Experiments on cats, dogs, and rats corroborated the statements of earlier observers, the injection of about one grain and a half rapidly leading to death without previous vomiting. The animals quickly became very weak, fell over to one side, and died in feeble convulsions in consequence of cardiac paralysis. The effects on the blood-pressure were precisely those described by Dr. Dyce Duckworth. He was unable to observe that the drug had any influence on the vagus.

SURGEONS PRACTISING DENTISTRY.

ALL medical men engaged in dental practice who value the reputation of their specialty, will thank Mr. W. A. N. Cattlin, the President of the Association of Surgeons practising Dental Surgery, for the bold and able way in which in his recent address he expressed his disapproval of an Act by which 5289 persons have been put on to a recognised dentists' register, only 533 of whom have given evidence of either a medical or a dental education. It is gratifying to hear from Mr. Cattlin that the sub-committee of his Association will use every endeavour to urge the Legislature to prohibit unqualified persons assuming the title of physician or surgeon alone, or in convenient and misleading conjunction with any other word or words. An evil principle has been acted on which may lead, if not soon disavowed, to still deeper injury to the

Digitized by Google

medical art. We may have surgeon bone-setters and surgeon corn-cutters if the reckless legislation of recent years is not vigorously opposed.

ORAL INSTRUCTION OF THE DEAF AND DUMB.

AN interesting example of the success which may attend persistent and well-directed efforts to overcome what at first sight appear insurmountable difficulties is afforded by the history of the Training College and School for the Deaf and Dumb in Fitzroy-square. One day last week a number of ladies and gentlemen assembled at Grosvenor House to witness the oral examination of sixty or seventy pupils of this excellent institution, under the direction of Mr. Van Praagh. Not very long subsequently to the commencement of the enterprise we took occasion to explain in some detail the nature of the system of lip-reading, by which deaf-mutes are taught to communicate their ideas in audible and articulate speech, and the results of the examination on the occasion referred to were such as to afford the liveliest gratification to the party assembled, and to reflect great credit on the director and his assistants for the patience and skill with which they have remedied, as far as is possible, one of the most grievous defects to which human beings are liable.

UNACKNOWLEDGED SERVICES.

THE people of London and the suburbs generally, especially those who pass most of their lives in the close atmosphere of densely populous districts, must have been a good deal astonished by the recent distribution of honours in the City of London. We say nothing as to the merits of the gentlemen who have just been knighted; our concern is with the neglect to honour one at least whose name has been identified with the timely rescue from enclosure and the preservation of fully six thousand acres of open airing and recreation ground in Epping Forest. When Mr. Nelson, the City Solicitor, took this matter in hand, he was almost alone in his work. The boon his enterprise has conferred directly on the pleasure, and indirectly on the health, of the people cannot easily be over-estimated. His services in the inauguration of the system of free bridges have been not less public-spirited, and deserve to be widely appreciated. Through a long series of years Mr. Nelson has laboured for the interests of the people of the metropolis; and it is strange, to the extent of being inexplicable, that his energy and achievements have been overlooked. Our own more immediate interest in the matter relates to the health aspect of the case. In the long and hard struggle to stay the spoliating activity of those who cared less for the preservation of open spaces than for other considerations, Mr. Nelson was ever, in his private, and as far as possible in his public, capacity on the side of the people; and it would have been only just and generous had his labours received the acknowledgment they deserve. We begin to think it is true that what happens is the unexpected.

ANIMAL VACCINATION IN INDIA.

AT a meeting of the Vice-Regal Council, held on the 20th February last, the Honourable Sayyad Ahmad Khan moved that the Vaccination Bill, which he had introduced on the 30th Sept., 1879 (see THE LANCET, Nov. 29th, 1879), should be referred to a Select Committee. The Bill, it will be remembered, if passed, would make vaccination compulsory, and it provides for vaccination from heifer lymph, as well as from humanised lymph, but gives precedence to the former sort of lymph, and permits the use of humanised lymph under certain specified circumstances only. The Bill, moreover, provides that it should have no force except in municipalities and cantonments, where adopted by the local authorities. It is, in fact, a permissive Bill. The promoter stated that the Government of India had now before it information from local governments, municipalities, and other sources, which would enable them to form a judgment as to its acceptability or otherwise. It was supported both by Hindus and Brahmans in a way to prove that it contained nothing inimical to their religious beliefs or practices; and he referred to an important statement of the Lieutenant-Governor of the Punjab, to the effect that a child of the age at which vaccination is practised is not, according to Hindu law, liable to ceremonial impurity; and therefore, even though vaccine may be impure to Hindus, the child would not be made impure by it. ' He denied that Dr. Cunningham's "Sanitary Primer" and his own Bill had for the first time made the source of vaccine matter known to Hindus at large, as asserted by the Punjab Hindu Association. Treatises on the subject, giving minute information as to the lymph, existed in the Hindi and Urdu languages, and had been published in 1860 and 1867. He again urged his argument for compulsion, observing that a hundred thousand lives are lost every year in India from small-pox. "In view of this awful fact," he said, "I must confess that I find it difficult to conceive how any vague apprehension and opposition, or the existence of unfounded prejudices, can have greater weight than the absolutely certain fact of the enormous loss of human life which is caused by the absence of a well-organised system of compulsory vaccination." After a brief discussion the Bill was referred to a Select Committee, with instructions not to provide for its introduction in any municipality or military cantonment, unless the authorities were satisfied that there was a preponderance of native opinion in favour of it, so far as could be ascertained.

STEEVENS'S HOSPITAL MEDICAL SCHOOL, DUBLIN.

THIS institution, which of late has not been in a very flourishing condition, may now be said to have collapsed, a result consequent on the recent action of the governors in filling up two vacancies in the hospital. For one of these Mr. Warren, lecturer on anatomy, and connected with the school for the past ten years, was a candidate, and although put forward by the medical committee, he was passed over by the governing body, who elected a gentleman very much Mr. Warren's junior. It is stated that several of the lecturing staff of the hospital have in consequence resigned their appointments in connexion with the school.

CONVENTION ON VITAL STATISTICS.

THE National Board of Health of the United States have issued an invitation to *all* (? within the limits of the United States) who are interested in vital statistics and charged with the duties of State or municipal registration to meet with it in Washington, on the 6th May next, for the purpose of considering the best method for the collection and publication of such statistics. The convention is more especially to consider mortality statistics, for which (the invitation states) it is extremely desirable to secure more uniformity than exists at present in nomenclature, in nosological arrangement, and in the forms of tables or graphic representations intended to show the relations of causes of death to locality, meteorology, sex, age, nativity, occupation, and birth-rate. Registrars of vital statistics are invited to forward to the Board as soon as possible, their suggestions as to nomenclature, blank forms, &c., including the following points:—1. Nomenclature. That of the Royal College of Physicians is suggested as best for present use, but if this be objected to, what substitute is recommended. 2. Copy of the State or municipal law or ordinance relating to registration of births

Digitized by Google

and deaths, with observations thereon. 3. Copies of blank forms and specimen pages of registers of all sorts used in registration, with observations relating thereto. 4. Forms of statistical reports recommended for use in asylums, dispensaries, hospitals, prisons, and other public institutions. 5. Forms for the registration of births, deaths, and marriages. 6. Opinions as to the registration of certain contagious and infectious diseases, stating diseases, and suggesting forms.

ROYAL COLLEGE OF PHYSICIANS.

AT the extraordinary meeting of the College on March 22nd, after the minutes of the previous meeting had been confirmed, the new regulations for the College Licence were finally approved. The President then addressed the Fellows on the completion of his year of office. James Risdon Bennett, M.D., F.R.S., was re-elected President of the College, and Dr. Wilks was admitted a councillor.

SMALL-POX IN DUBLIN.

FOR many months an epidemic of small-pox has existed in this city, the deaths averaging about five each week. Although the mortality is slight, yet the continuance of the epidemic after so many months reflects unfavourably on the sanitary authorities. Neglect of vaccination seems to lie at the root of the evil, for the relieving officer of the South Dublin Union recently reported that there were 260 non-vaccinated children in the Union. Dr. MacCabe, Local Government Board Inspector, has recommended that twelve of the most respectable defaulters should be prosecuted, as there was no prospect of small-pox dying out in Dublin so long as such a state of things was permitted to exist. This suggestion has been adopted, and it is also probable that a special prosecutor will be appointed for these cases of neglect of vaccination.

A GRIEVANCE OF SICK PAUPERS.

THE REV. H. A. GOODWIN of Sambourne Rectory, Romford, gives prominence in the *Chelmsford Chronicle* to what was really a hard case, and which, we fear, is only one of a considerable number. A decent labourer, fifty-five years old, one of whose clubs had failed, and who had become superannuated in another, had to fall back on the parish doctor, to whose skill and kindness Mr. Goodwin testifies. But the rector ascertained that before the order for the doctor and medicines could be procured forty-one miles had to be travelled, of which the wife walked twenty-nine. These facts need no comment, and call attention loudly to a great evil. Even in London there are distances to be travelled which imply great hardship to poor and ill-tended people. It is not by such penances that unprincipled paupers are to be punished, and they are unworthy of a Christian country in the case of decent and injured people like the above labourer.

BRIGADE DEPOTS: MEDICAL OFFICERS.

A GENERAL ORDER just issued lays down that medical officers on half-pay, or otherwise retired, who are appointed to the medical charge of Brigade Depôts, are while so employed to wear the uniform of the Army Medical Department as laid down in the Dress Regulations, 1874 (amended by G.O. 3, 1880), according to their rank on retirement, or the honorary rank they now hold.

A MELANCHOLY and fatal accident to the Professor of Chemistry at the Grenoble Lyceum is reported. In the course of his lecture the professor, to moisten his mouth, took up a vessel which he supposed to contain *eau sucrée*, and drank so much of a mercurial solution that death ensued almost instantly.

AN official inquiry has been held by Captain Hildyard, Local Government Board inspector, as to the expediency of permitting the Town Council of Salisbury compulsorily to acquire land for the formation of a sewage farm, Mr. Jervoise, the owner of property adjoining the present drainage outfall having taken steps to prevent the flow of sewage into his river, under the Rivers Pollution Act. It was stated that the total cost of purchase and the erection of the necessary works will be £80,000. The inspector said he would report on the subject to the Local Government Board.

WE have pleasure in learning that the Justices of Surrey have recognised the important services of Dr. Brushfield, as superintendent of the Brookwood Asylum, by an addition to the salary of his office, which brings it up to £1000 a year. Dr. Brushfield opened the asylum, himself planned, and superintended the construction and furnishing of the new buildings added in 1875, and has conducted the institution for now fourteen years with credit to himself and advantage to the county.

THE Sunderland Local Board has called attention to the 252nd section of the Public Health Act, which would appear to require amendment. That section enacts that any legal proceedings for breach of building bye-laws must be taken within six months of the date of the committal of the offence. Of course many infringements of the law are not discovered until after the expiration of the time stated, so that the limitation referred to obviously cripples the powers of the Act for good.

THE outbreak of fever in Hare Island to which we referred last week has turned out to have been much exaggerated, and it appears on reliable authority that there were only twenty-nine cases affected, of which twenty-eight are under twelve years of age. Also that the disease is of a very mild type, and that there have been no additional cases for the past week. The origin of the epidemic cannot be traced.

SURGEON-MAJOR FRANCIS P. STAPLES has been compelled by ill-health to resign the appointment of Assistant Professor of Military Surgery at the Royal Victoria Hospital, Netley. He will be succeeded by Surgeon-Major Richard Tobin, who has officiated for the last six months.

THE "Watsonian Gold Medal, with five sovereigns," given annually by the Faculty of Physicians and Surgeons of Glasgow, to the gentleman who gains the highest average marks at the primary examinations, has been awarded this year to Mr. George W. Till, of Anderson's College.

MR. E. E. PHILLIPS, L.R.C.P. Edin., of Southend, has, we regret to learn, met with a serious accident, by the vehicle in which he was riding coming into collision with a cart. Mr. Phillips was thrown to the ground and sustained a fracture of the leg.

WE regret to report the death on the 17th January, at Lahore, of Surgeon-Major W. Eddowes, Indian Medical Department, in charge 30th Bengal Native Infantry, and for many years medical officer of the 2nd P. W. O. Ghoorkas.

ON the 19th inst., at the Freemasons' Tavern, Major Graham, the late Registrar-General, was presented with a life-size portrait of himself, executed by Mr. Frank Holl, A.R.A.

DURING the week ending February 28th there were three fresh outbreaks of pleuro-pneumonia in Essex. Of swine fever there were twenty-eight fresh cases in the county.

Digitized by Google

THE

INFECTIVE DISEASES KNOWN AS PYÆMIA, SEPTICÆMIA, AND PURULENT INFECTION.[1]

(Continued from p. 286.)

IN the second part of this report we are presented with an elaborate analysis of what for want of a better term may be styled the natural history of septic diseases. Dealing with a large number of cases, the committee have aimed at interpreting their phenomena in the light afforded by experimental research. The idea is worked out so thoroughly as to leave little to be desired, and doubtless the plan laid down will be followed in the future. The more this portion of the report is studied the more clearly will its intrinsic value be appreciated. It is almost the first satisfactory attempt to clear away the obscurities which have shrouded the conditions of septicæmia and pyæmia; and difficult as the task must have been, it has been performed with a considerable measure of success, both in the direction of suggestion for further work, and in the actual settlement of doubtful points.

The opening paragraph of this section states that in it an attempt has been made to divide cases of septicæmia and pyæmia in the human subject into sharply defined groups corresponding in their clinical features and naked-eye morbid appearances to diseases of the same kind artificially produced in animals.

Septicæmia.—The various definitions that have been given from time to time are stated. Dr. Sanderson defines it as a constitutional disorder produced by the entrance into the blood of a quantity of septic material, as a disease of definite duration, in which the poison has no tendency to multiply in the organism. Davaine includes under it every case of death following the entrance of putrid substances into the blood without the formation of local centres of inflammation or suppuration. Koch all those cases of general infection from wounds in which there are no metastatic changes. Birch Hirschfeld regards it as a process of poisoning; Hueter—as a fever caused by the entrance into the circulation of products of putrefaction from local centres of decomposition; Billroth—as an acute general affection due to the taking up of various kinds of putrid substances into the blood; whilst the various authorities in this country, looking mainly to clinical characteristics do not recognise any sharp distinction between the various forms of blood-poisoning.

The experimental researches of Koch have, however, led the way to the recognition of two distinct forms of septicæmia. His experiments made on the mouse showed that when a sufficient dose of putrid blood was injected subcutaneously death rapidly followed in a few hours, as from a virulent poison. In such cases, he declares that no organisms arise in the blood, that the poison does not multiply, and that the disease cannot be transmitted by inoculation. He would style this form *septic intoxication*. But if a very small dose of the poison be administered, either no effects follow, or else the animal becomes weaker and dies at the end of forty to sixty hours, with swollen spleen, and fluidity of blood, which teems with organisms and is highly virulent. This is true *septic infection*, and finds its parallel in most cases of human septicæmia.

The conditions favourable to septic intoxication in the human subject are two—viz., a sufficient quantity of septic matter to furnish the fatal dose, and the presence of conditions favourable to rapid absorption. On the first head there are no reliable data; but it is surmised that the quantity required to be absorbed to produce rapid death from intoxication would be from one to two ounces of putrifying blood or serum. The means for its rapid absorption would be those afforded by raw surfaces before they are covered with healthy granulation tissue, and therefore acute septic intoxication would be favoured by large and irregular wounds, as those resulting from compound fractures; hollow wounds, as those left after the removal of tumours; wounds of joints, of large serous sacs, and large abscesses opening externally by an insufficient aperture. The accumulation of septic matter in the uterus after delivery; in the peritoneum after ovariotomy are favourable conditions. It is suggested that cases of death in the forty-eight hours after ovariotomy are probably due to this cause, which the adoption of antiseptic measures and drainage has almost eliminated.

The evidences of fatal acute septic intoxication in man would then be based upon the presence of a sufficient quantity of septic matter to yield the necessary dose of the poison; the invasion of the symptoms at a time when decomposition of the discharge has commenced, and before the surface of the wound is covered by granulations; the occurrence of high fever, followed by great depression; post-mortem appearances, indicating a tendency to congestion and capillary hæmorrhage; and probably also the absence organisms from the blood during life, or immediately after death (Koch). Out of twenty-eight cases of septicæmia there was only presumptive evidence in two instances that the patient died from this form of blood-poisoning. The one was a case of tumour removed from below the lower jaw, and the cavity became distended with foul discharge, death taking place on the third day with dyspnœa, but no rigors, vomiting, or diarrhœa. The patient was a woman aged seventy-four, and the autopsy showed blood-staining of the endocardium, pale and softened liver and spleen. The other was a case of death on the third day, after an abscess of the patellar bursa had been opened. It seems probable that had cases of ovariotomy been included several other instances of true septic intoxication could have been gathered. Still, enough has been done to show that this is a definite form of blood-poisoning; and it seems to us to be one of the chief gains derived from this report to have clearly brought this into view.

Between this condition and that ordinarily known as septicæmia—viz., "septic infection without metastatic inflammation," there are marked contrasts. In "septic infection" the poison appears to multiply in the organism, and its effects are not directly proportional to the dose. Nothing is definitely known concerning the exact nature of the poison, but the researches of Koch (borne out to a certain extent by the committee) are in favour of the view of its dependence on the presence of a microscopic organism which multiplies in the blood, like the bacillus of splenic fever. The post-mortem appearances of fatal cases are chiefly those of congestion of internal organs, especially of the spleen, together with subserous and submucous petechiæ. The conditions indicative of it in man would be the occurrence of a wound of such a size as to render it impossible for the necessary fatal dose of septic matter to be found in it, the evidence of infection by inoculation from one patient to another, and the presence of large numbers of bacteria in the blood during life or immediately after death. In the case of large wounds it would be more or less complicated by septic intoxication. A minute dose of a very virulent poison found in decomposing discharges might cause death without any process of multiplication in the body of an affected animal; but in that case it would lose its virulence by repeated inoculation, the reverse of that which happens in true septic infection. Out of the twenty-eight cases there were only two in which the wounds were so small as to exclude the possibility of sufficient septic matter being present to yield a directly fatal dose, one being a case of death after ligature of a small epithelioma of the tongue, the other a case of dissection wound.

The period of invasion in all the cases of septic infection varied from two to twenty-two days. In all but two cases rigors were marked, and mostly repeated more than once; and the other most frequent symptoms include delirium, sweating, diarrhœa, dyspnœa, and icterus. The post-mortem appearances were chiefly congestion of the lungs, swelling of liver, spleen, and kidneys.

It is concluded that further investigation is necessary to ascertain whether any distinct separation can be made clinically as well as experimentally between septic intoxication and septic infection. Septic intoxication should be absolutely preventable, depending, as it does, upon the accumulation and decomposition of discharges in a wound of considerable size, whilst in septic infection a virulent poison is produced capable of transmission from patient to patient.

Pyæmia.—Here, again, the word has been used in different senses, and it is pointed out that, "although it would be much better if the word was entirely discarded and some other found in its place, it is very difficult to suggest any

[1] Report of the Committee appointed by the Pathological Society of London to investigate the nature and causes of those infectious diseases known as Pyæmia, Septicæmia, and Purulent Infection.

Digitized by Google

that would be free from objection," and the definition given by the College of Physicians in the nomenclature of diseases—viz., "a febrile affection resulting in the formation of abscesses in the viscera and other parts"—is sufficient to make clear the clinical meaning of the term.

After a brief sketch of the experimental researches on pyæmia, the report proceeds to an analysis of the cases collected by the committee. No fewer than ten groups have been made, and we can do no more in this place than give the headings of these classes, for the report is so concise and so full of detail as not to admit of analysis within the limits at our disposal. The first group includes—1. Cases of pyæmia, secondary to an open wound in which there is no evidence that the secondary inflammations are due to embolism, comprising (*a*) cases in which visceral abscesses are wanting, and (*b*) cases in which visceral abscesses were present, but no softening thrombus found at the primary seat of disease. 2. Cases in which venous thrombosis occurred apparently as one of the secondary affections. 3. Cases in which venous thrombosis and softening of thrombus occurred without giving rise to embolism or secondary abscesses. 4. Cases in which venous thrombosis and softening of the thrombus occurred, with secondary abscesses in other viscera, but not in the lungs. 5. Cases in which venous thrombosis with softening of thrombus occurred, with abscesses in the lungs and in other viscera. 6. Cases in which venous thrombosis and softening of the thrombus occurred, with embolic abscesses in the lungs only. 7. Cases of "pyæmia" secondary to infective periostitis. 8. Cases of "pyæmia" secondary to infective endocarditis. 9. Infective myositis. 10. Spontaneous septicæmia and pyæmia.

The conclusion arrived at from this minute and exhaustive analysis of cases of septicæmia and pyæmia is characterised by the true spirit of scientific caution. "It is quite certain that our knowledge is not yet sufficiently advanced to justify the assertion that all these various forms are only modifications of one disease. If such an assertion can ever be proved to be true it can only be when the exact nature of every form is perfectly understood—a time which we venture to predict is still far distant"; and it is, moreover, pointed out that instances of apparent merging of one form into another can be equally well explained on the supposition of "the coexistence of two or even more of the foregoing conditions in the same case."

THE DISPUTE AT GUY'S.

THE questions which have arisen out of the change of nursing system lately introduced at Guy's Hospital were submitted to a General Court of the Governors, which assembled for the purpose on February 23rd and on March 3rd, 10th, and 11th. The following letters addressed by Sir T. Dyke Acland to Lord Cottesloe will show in some degree how the discussion was conducted, how narrow were the questions submitted to the Court, and how, between the fear of offending their treasurer and increasing the feeling which had naturally arisen among the members of the staff, the decision arrived at was very much of the nature of a compromise. It does not, we confess, seem likely to produce more than a temporary calm, seeing that the office of treasurer is still virtually one of dictation, and that Sir T. Acland's sensible opinion "that no power can be allowed within the hospital to be independent, in the sense of being without superintendence, or check, or appeal," has been passed over by the Court. Subjoined are the letters.

Letter from Sir T. DYKE ACLAND *to* Lord COTTESLOE.

16, Suffolk-street, Pall Mall East, March 13, 1880.

Dear Lord Cottesloe,—I hope I may be acquitted of presumption if I respectfully submit to the treasurer and governors of Guy's Hospital, through you, as chairman of our meetings in the absence of the president, my view of our present position.

You opened our proceedings on the 3rd inst. with the wise advice that we should not dwell on the past, but look to the future well-being of the hospital, which we all desire. At the close of the verbal communications of the medical staff, of the medical superintendent, and the matron, I heard, with a feeling of deep disappointment, that before we could enter on any future arrangements we must first adjudicate on what has passed.

I ask with all respect a question suggested by an eminent governor, "What is the issue?" We have had before us a long letter full of complicated details, inferences as to the construction of rules, hypothetical forecasts of ulterior intentions; on the other hand, marginal rejoinders, of which I will only say that they include severe accusations as to the conduct and even the spirit of the staff. We have heard speeches eloquent and manly, if not always couched in language showing the discretion of practised advocates, exhibitions of strong feeling, and full personal explanations; there have not been wanting, moreover, hints of suggestions prompted by various persons not before us. Is it desirable that we should attempt to come to a formal adjudication on such data? Is it likely that we shall be unanimous in our verdict? Can we not rather follow your opening counsel, and act in a manner more befitting the president, treasurer, and governors of Guy's, as one undivided and even now unquestioned authority?

It must be obvious to the governors that there has been much misunderstanding, much incorrect information, much high colouring of insignificant details. It seems to me most undesirable to express a formal opinion as to the causes which have led to these unfortunate misconceptions. I think, however, that after eliminating these disturbing influences we may arrive at some tangible results which are not in dispute. And yet it would seem hardly expedient for the governors to state such results in an abstract form by way of reply to the written or verbal communications brought before them.

It seems to be admitted:—1. That the medical treatment of the patients is the first object of this hospital; the advancement of science, in conjunction with the practical teaching of medical students, the second; the training of nurses the third, subordinate to the two first, but indispensably required by modern opinion. 2. That the ward system, as defined by Sir W. Gull, with the assent of Dr. Pavy, may and ought to be continued. 3. That some central authority must be responsible for the supply and training of nurses. 4. That the orders of the medical staff as to any matter affecting the treatment of their patients, must be implicitly obeyed by the sisters and nurses, and not interfered with by anyone else. 5. That any complaints of the medical staff as to the nursing should receive immediate attention, without needlessly taking up their time. 6. That no power of control can be allowed within the hospital to be independent, in the sense of being without superintendence, or check, or appeal. 7. It is important to note that the matron, in reply to definite questions, disavowed the claim to make rules irrespective of the chief hospital authority, and that she expressed her willingness that any complaints about the nurses should, in the first instance, if so desired, be lodged with the medical superintendent.

These principles, reasonable as they may appear when stated, have been slowly wrung out of the facts by discussion. It may be excusable if, under the circumstances of the estrangement between the staff and the matron, they seemed to be called in question.

It seems to me that the staff were not only excusable for stating, but were under an obligation to illustrate, the grounds of their apprehensions. Having done as they were required to do, though possibly not always in cautious language, still with no apparent disrespect to the treasurer and governors, they took the wise course of closing their verbal communications by reading the well-considered letters of their spokesman, Dr. Pavy, and of Sir William Gull. Nor is it irrelevant to notice that a junior member of the staff (especially called upon) practically abandoned the ground of personal objection to the matron. The staff then left the whole matter unreservedly in the hands of the president, treasurer, and governors.

Under these circumstances I venture most respectfully but earnestly to repeat my suggestion, that we should pass on at once from anything like judicial investigation into the region of practical administration for the future, and, to speak more particularly—1. That opportunities be given to the staff to offer suggestions, either individually or through a small deputation. 2. That measures be taken without delay to establish free communication between the medical staff and the matron, either directly or through the medical superintendent. I do not venture to make any suggestion as to the official machinery by which these ends are to be

Digitized by Google

obtained, whether through the treasurer, who possesses our confidence, through the court of committees, or through a special committee.

I reserve for verbal statement on Wednesday some serious considerations as to the need for watchfulness with reference to the growth and future development of the changes recently introduced, beneficial as I believe them to be, if carried out with discretion and with the co-operation of all concerned.

I am, dear Lord Cottesloe, yours truly,
THOMAS DYKE ACLAND.

Extract from the Minutes of a General Court, held on 17th March, 1880 :—

Read proceedings, dated February 25th, March 3rd, 10th, and 11th.

Resolutions :—

'1. That the Court, while fully appreciating the anxiety of the medical staff in regard to the possible introduction of any changes likely to affect the well-being of the hospital, have great satisfaction in recording, as the result of the recent inquiry, that, in their opinion, no fundamental changes contrary to the rules of 1874 have been made, and that the matron has not exercised any authority in this respect without consultation with the treasurer and the superintendent. Certain changes of an administrative and domestic character have indeed been ordered. Some of these have been carried out, some have since been given up, and some are still under consideration.

'2. That the measures now in progress for the improvement of the supply and training of nurses, if carried on with due discretion, with consideration of the wishes of the medical staff, and with their co-operation, will tend to promote the well-being of the patients, and to sustain both the hospital and the medical school in public estimation.

'3. That the treasurer having already expressed his desire to take the opinion of the medical staff on such changes which seem still open to adjustment, the governors request the treasurer and court of committees—the appointed executive authority of the hospital—to invite the attendance of any of the medical staff to meet them and the superintendent and the matron, with a view to the recommendation of such administrative details as may best secure the efficiency and harmony of the internal arrangements of the hospital.

'Ordered that a copy of the above be communicated to the medical staff.

ED. H. LUSHINGTON, Secretary.

Correspondence.

"Audi alteram partem."

IS INSANITY CAUSED BY "DRINK"?

To the Editor of THE LANCET.

SIR,—DR. Mortimer-Granville's honest and comprehensive letter upon this important question which appeared in THE LANCET of February 21st—a question which is so misunderstood by many if not by most observers—suggests points worthy of consideration, and in writing this letter I am merely acting upon his advice when he says—"The relation between drink and insanity should be discussed on the basis of *records of practice* without prejudice or a preconceived opinion." In my asylum practice during a period of seven years, I had an unqualified opportunity of observing the relationship which exists between "insanity due to alcohol as a cause," and "alcoholism due to insanity as a cause." I may perhaps regret that I have no absolute statistics to guide me or to confirm my opinion, but I cannot say that I am sorry for this defect, as the greater part of the evidence of patients themselves in all matters relating to drink and insanity and other nervous affections is often worse than valueless, because in the majority of instances it is an utter perversion of truth. So that I am inclined to think that any careful, honest observer, of ordinary knowledge and grasp of character, is better able to form an opinion relative to cause and effect, if he applies himself thoroughly to elucidate facts by indirect methods of research, than by his taking the statements of patients as absolute.

In dealing with the causation of disease, I hold that we ought to consider, firstly, how far the diseased condition is due to the inherent or determined cause. Secondly, how far it is due to the exciting assignable or determining cause. We often see and read of men of large experience who write and speak of paraplegia caused by drink, or of epilepsy caused by drink, or of insanity caused by drink, or of paralysis caused by syphilis, and they even go so far as to raise *dicta* upon such presumptive evidence. I must say that, from a legal point of view, there may, perhaps, be some difficulty to substantiate a doctrine founded more or less upon what may be to a legal mind "an assumption," but to one skilled in clinical medicine it is nothing more than a rational and scientific, although probably a technical, deduction. The relationship between drink and insanity in reference to *cause* and *effect* may, I venture to conclude, be viewed in a somewhat similar light to the foregoing proposition, and, as psychologists and physicians, we must not fail to take into consideration the functional mental derangements and loss of physical power, which are caused by exhaustion and want of nutrition of the nervous centres, and which we find occasionally in the habitual drunkard, and frequently in the confirmed dipsomaniac.

My experience of the dipsomaniac is this—that he is a person of feeble, and in fact defective, nervous organisation. He may be a man of quick or even brilliant intellect, but withal he shows a feebleness of mind and instability of character which render him peculiarly sensitive and impressionable to his surroundings. He is impulsive, vacillating, and emotional, easily led, but not so easily driven. He has a passion and a craving for drink over which he has no control, and, like a ship at sea without a helm, he is driven about by every turn of tide and change of wind.

If drink were the great *cause* of insanity (which I do not believe), rather than the *effect* of an inherent enfeeblement of the mind (which I believe it to be), we ought to have, as Dr. Mortimer-Granville says, some more distinct and decided evidence of those pathological changes in the connective tissue of the brain which we find do arise from the effects of alcohol in other structures of the body. Yet I am not one of that class of observers who believe that a hard, cirrhosed liver or kidney must of necessity be due to alcohol, and my experience has guided me to this conclusion.

There are few observers, however, who will not readily admit that insanity and drink are in some cases so associated—I might almost say correlated—that it is almost impossible by any obtainable evidence to draw the line between cause and effect with any amount of accuracy.

The morbid craving for drink which is the marked characteristic of the dipsomaniac is undoubtedly in itself a species of insanity, and does in the course of time lead to confirmed insanity in some more objective form than that of dipsomania. But this morbid craving for drink which we find in the dipsomaniac is merely an instance of a defective and unstable mental process, and in all probability the would-be lunatic, if he had not originally a morbid craving for drink, would evince a passion equally as morbid in some other given direction; and it is on this account that we are being constantly reminded that the cause of So-and-so's insanity is drink, or masturbation, or impotency, when in fact these conditions are due to a weakness and inadequacy on the part of the nervous centres, which are inductive of morbid tendencies, and which become by a process of development the factors which eventually bring about that dissolution and disorganisation of those occult attributes of the mind through which a man becomes branded by the term "insane."

I am, Sir, yours obediently,
THOMAS STRETCH DOWSE.

Old Burlington-street, March, 1880.

COMPARATIVE PATHOLOGY.

To the Editor of THE LANCET.

SIR,—Kindly allow me space for a few comments on the remarks which have recently been made in THE LANCET, in reference to Comparative Pathology.

In the first place, I would call attention to the sweeping assertions so often made as to the dependence of some endemics and epidemics upon the existence of enzootics and epizootics; it is well known to all observant veterinary surgeons that epidemics and epizootics frequently co-exist, and it is equally well known that the latter may take prece-

Digitized by Google

dence, in point of time, of the former, or *vice versâ*; but that either are dependent upon the other for their origin is a gratuitous and hypothetical statement.

The existence of an epidemic or epizootic atmosphere—if I may be permitted the use of such an expression—is equally operative in the production of this class of diseases in both cases; in other words, the atmospheric influences which produce epidemics originate epizootics likewise.

In the second place, I would express my concurrence with the majority of the opinions recently advanced by Mr. Fleming in reference to variola, and would also call attention to some facts which have come under my notice at different times as to the prevalence, in England, of variola vaccina.

Some nine or ten years ago I saw cases of this disease in the neighbourhood of Blackburn, in which district it was well known. During the past eight years I have occasionally met with typical cases in the dairies of Edinburgh and Leith, and, with the exception of a few, all have passed through a regular course with but very slight apparent illness, or diminution of, or interference with, the lacteal secretion.

So little is the milk altered in its characters that it is a very rare occurrence for it to be kept separate from the daily yield. I have myself, on several occasions, examined such milk very carefully, microscopically, and otherwise, and in no instance have I been able to detect any material departure from the normal condition.

If small-pox were dependent upon variola vaccina for its existence we should expect that it would be unusually prevalent in Edinburgh and Leith, particularly amongst the families of cow-feeders. I believe I am justified in saying that such is not the case.

All the cows which suffer from variola vaccina in this neighbourhood are brought from North Lancashire (collected usually at Preston from the surrounding districts), from Cumberland, and Westmoreland, hence it should be an easy matter for medical men residing in these counties to institute inquiries as to the relative prevalence of small-pox and variola vaccina.

The remark made in your issue of February 28th, by Dr. H. D'O. Foote, to the effect that the animals which he saw suffering from V. vaccina were sickly, thin, and miserable, is probably to be explained by the treatment to which they had been subjected. I have observed in my book on "The Four Bovine Scourges," that when cows are cared for during the febrile stage of eczema epizootica the suffering is comparatively slight, but if they had been subjected to exposure or hardships in travelling the fever is aggravated and the subsequent results very grave. The same remarks apply equally to V. vaccina. As to the measles of pigs, I have frequently observed rubeolous affections in these animals running through a course almost identical with that of measles in the human subject, and have looked upon such cases as in every sense analogous to that exanthem.

Canine variola is often met with here. Lastly, in reference to the remarks recently made by Charcot as to the prior existence or otherwise of a localised pneumonia in pulmonary tubercular disease, I may observe that whatever may be the case in the human subject, we seldom find traces of a previous pneumonia in the tuberculous lungs of cattle.

I am, Sir, your obedient servant,

THOMAS WALLEY,

Principal, Royal Dick's Veterinary College, Edinburgh.

ANIMAL VACCINATION IN INDIA.

To the Editor of THE LANCET.

SIR,—In the note on "Animal Vaccination in India," which appeared in your issue of the 24th of January last, you appear to share the fears of the Punjab Hindoo Association in regard to the loss of caste which a Hindoo would incur in consequence of being vaccinated from lymph taken from the teats or udder of a heifer or cow. Permit me to observe, that if this matter may be judged by the practical experience of Bombay, the most populous city in India, these fears are perfectly groundless. Compulsory vaccination, and chiefly animal vaccination, has been established here for the last three years; the lymph used is mostly that from the udder of the heifer. Not only has objection to this lymph not been taken by the Hindoos, but animal vaccination is preferred to arm-to-arm vaccination. The people are quite pleased, because their vaccinated children are not usually required to contribute the lymph for extending the system. The Guzerathee portion of the Hindoo community of Bombay are quite as full of caste prejudices as any other Hindoos in British India, and yet they accept vaccination from the heifer as an unmixed blessing. The prejudices of the Punjab Hindoos appear to me to belong to Buddhism. When, several centuries ago, Brahminism regained the ascendancy in India and displaced Buddhism, some of the minor prejudices of the latter sect were necessarily transferred with the change; and this fear of heifer vaccination may be one of these prejudices. In Sanscrit literature the ordinary name for a guest is cow-killer; and no feast is said to be worthy of the name at which animal food was not provided.

Be this as it may, nothing has yet occurred to induce the Government of India to withhold a Compulsory Vaccination Act; nothing to prevent the free use of animal vaccination in any town or city in this country. Considering the vast benefits which a complete system of vaccination would confer upon India, it seems to me to be a matter of much regret that any educated public Hindoo body should engage itself in searching out fancied objections to animal vaccination at a time when the very life of the country requires that if any appeal is made to the people at all it should be an appeal to reason and common sense rather than to the spurious literature of an effete age. It is true in India that whenever Government have passed a well-considered law, which even the ignorant ryot can perceive will benefit all classes of the people, all prejudice has been at once forgotten, and a loyal obedience has been at once rendered. This has occurred in Bombay with the Compulsory Vaccination Act, and it will occur everywhere else in the country if Government has the courage of its opinion.

Whether arm-to-arm vaccination is to be preferred to animal vaccination is not now the question. Bombay experience is in favour of animal vaccination, especially amongst the poor with skins more or less diseased; but time is required before its protective influence can be accurately determined. If a Hindoo can be found weak-minded enough to object to animal vaccination, the remedy is at hand, and he may have his choice of human lymph, but such a man will have to meet a Hindoo vaccinator.

I trust, Sir, that the importance of this subject to the unvaccinated hundreds of thousands of the people of India will secure for my remarks a place in your widely-circulated journal.

Yours faithfully,

THOMAS BLANEY,

Bombay, Feb. 14th, 1880. Chairman Bombay Town Council.

TRANSVERSE DEPRESSIONS ON THE NAILS.

To the Editor of THE LANCET.

SIR,—The point in Dr. Thin's communication of the 20th inst. is of some clinical and medico-legal importance. Several observers have recorded cases to illustrate the dates of appearance and progress of these furrows. In particular, Dr. Wilks and Dr. Langdon Down have contributed facts bearing on this subject.[1] I have often observed the course of these depressions, and am inclined to agree with the recorded statements. I think, however, that there is a rather more rapid formation of nail than that of two complete growths in the year. Certainly, the rate of formation varies in different people, and at different seasons of the year. It is also influenced by the habits and occupation of the individual.

I am, Sir, your obedient servant,

DYCE DUCKWORTH, M.D.

Grafton-street, March 22nd.

THE RANK OF THE DIRECTOR-GENERAL OF THE ARMY MEDICAL DEPARTMENT.

To the Editor of THE LANCET.

SIR,—While the Director-General has been fighting and winning battles for the benefit of his brother officers, he has forgotten to claim justice for himself. I allude now to the very inferior relative rank granted this officer. As you are aware, every surgeon-general of the Army Medical Department ranks with a major-general in the army—a fair and just rule; but the Director-General of the whole department

[1] Vide Mr. Hutchinson's Lectures on Clinical Surgery, 1878, p. 144.

Digitized by Google

who has control over these officers, and their very appointment in his hands, has but the same relative rank of major-general.

Now, any day, if a surgeon-general low on the list was made Director-General A.M.D.—a by no means impossible occurrence,—we would see the strange sight of the Director-General being junior in the army to one of his own subordinate officers. It needs no knowledge of organisation to see that there is a mistake here.

The Director-General, on appointment, should have the relative rank of a Lieutenant-General; and on retirement he should, if he have done the State good service, get the further honorary rank of a full General in the army. In a short time the Director-General A.M.D. will have the great Native Army of India also under his control, and will be a most powerful officer.

I hope you will support the view that his rank is now inferior, and move the authorities for its being changed to its proper position. Yours, &c.,

March, 1880. I.V.R.C.

THE AFGHAN CAMPAIGN.

(From a Correspondent.)

THE fighting of the tribesmen round Cabul ceased on the 23rd December, and they withdrew to the Highlands of Kohistan and Ghuzni. The exposure endured by our men during the twelve days of fighting has told heavily upon their strength, and there are now more than 700 men, native, European, and followers, in hospital. Pneumonia is the prevalent disease, and is the cause of many deaths. The 92nd Regiment particularly has suffered from this disease.

The British Field Hospital is placed in an angle of the Sherpur Cantonment, and all the sick are in houses, and have plenty of fires, warm clothing, and food. Medicines too are ample, although in the fighting much medical and surgical equipment was lost when the forces fell back on Sherpur.

The Field Hospital system here, and along the Khyber Line, has worked well, although it is true that the labour it entails on the Field Hospital Staff is very heavy. There is, of course, one medical officer with each corps or battery, but their work is very light, and the general opinion seems to be that the younger officers should be placed in these billets. It seems impossible to exaggerate the fatigue and labours of the Field Hospital work, and it is quite certain it will always be hard work in any campaign. To march a Field Hospital full of sick, to choose the camping ground, pitch the camp, arrange for the feeding and nursing of the sick, the shelter and feeding of the staff and servants, the due care of the transport animals, and the management of the large following of doolie bearers, is trying work.

It cannot be forgotten either that the Medical Department has often an uphill labour to perform in carrying out its duties, owing to the want of due aid being given to it by other branches. Up to the late campaign of 1878 staff officers in India were not required to take any special notice of the hospitals—that is to say, the hospital as a unit in the *army* was not thought of, as each *regiment* had its own hospital, which pitched its camp in the rear of its battalion without any further question. Now, however, with this new system the Field Hospital as a unit takes its place in the line of the camp, and becomes a very perceptible item in the general camp.

One great advantage that exists this year is that all the medicines, instruments, purveyors' stores, and records of the hospital are carried on mules, in regular mule-boxes. Last year camels were used, and caused much trouble to the medical officers from their slowness and inability to keep pace with the marching column.

An order is needed directing that mules once issued to a Field Hospital for this duty should remain with it during the campaign, as now a battle has often to be fought with the Transport Department to prevent these mules being sent away at every halt in an encampment.

The Gandamak Field Hospital in its march to Cabul was completely carried on mules, and it kept its place behind the reserve ammunition throughout the whole of the march over very trying passes from 6000 to 7000 feet high without a single mishap. The order of march was as follows:—1. Medicines packed in mule gakdans, or paniers. 2. Puckals or water skins on mules, a most important requirement. 3. The office record. 4. Purveyors' stores—all packed in boxes except the blankets, which were carried in rolls on either side of mules, twenty-five on each mule. 5. Light mountain tents, two on each mule, well rolled up, and packed on the pack-saddles. 6. A mule carrying the cooking pots, rations for the day, or beef-tea ready to be heated. 7. A mule carrying camp colours, picks and shovels, on one side, and on the other the bed-pans, urinals, &c. Eighth in order: officers' baggage and mess equipment, then servants' baggage.

About seventy mules were needed for the hospital, but several of them carried grain and food for man and beast for several days. In addition to these mules thirteen camels were used, carrying hospital marquees of a larger size, but these often did not arrive on the ground till five or six hours after the light mule hospital following the column had come in.

When the campaign is over (and every one is heartily sick and tired of it) no doubt we shall have many papers on hospital working in the field, from the officers serving with them.

A secretary for the P.M.O. of each Division has been sanctioned in a kind of way. Last year THE LANCET drew attention to the want of such an officer, and doubtless the notice has done much towards getting even the present indefinite sanction of the appointment. It cannot be impressed enough on the authorities that the P.M.O. of a Division does need a secretary to assist in the routine of office duties.

The want of an Army Hospital Corps is very much felt also. The present ignorant followers, called Hospital Servants, are wretched creatures, and should give place to well-trained and disciplined men with good pay and pensions. The want of mule carriage for ailing or slightly wounded men is also an urgent matter, as the vast army of undisciplined doolie bearers need to be cut down very much. We all hope for great things when this war is over. I have not met one man, from the highest to the lowest, who does not hate Cabul and want to get away from it.

Cabul, 18th Jan. 1880.

New Invention.

THE "CARMICHAEL" PORTABLE BOOT-TREE.

THIS is a very simple, interesting, and useful invention. A boot is constructed of india-rubber cloth, or, rather, a cushion in the shape of a boot; and when inflated with air it acts as a boot-tree. The advantage is self-evident. When the tree-cushion is empty it can be folded to form a very small package, and when required for use it can be introduced into the boot, when only partially distended, without straining the leather, as happens when a wooden tree is employed. This latter point, though not apparently specified by the inventors, strikes us as of no small importance. To country medical practitioners, sporting men, officers on campaign, travellers generally, and careful people in particular, the apparatus will commend itself as meeting a long-felt need very efficiently. The agents are Messrs. W. Sparkes Hall & Co., 310, Regent-street, London.

Obituary.

THOMAS BELL, F.R.S., F.R.C.S., F.Z.S., F.L.S.

MR. THOMAS BELL, whose death we recorded last week, was the son of a surgeon in large practice for more than fifty years at Poole, in Dorsetshire. He was born on the 11th of October, 1792. He commenced his professional studies with his father. In 1813 he proceeded to London, and attended the practice of Guy's and St. Thomas's Hospitals in the time of Mr. Cline, Sir Astley Cooper, Mr. Travers, and other celebrated surgeons of that period. In 1815 he passed the College of Surgeons, and in 1817 began lecturing at Guy's Hospital on the Anatomy and Diseases of the Teeth. He was appointed at the same time Dental Surgeon to the Hospital. He also gave lectures on Comparative Anatomy in

Digitized by Google

the same school. Mr. Bell resided for many years in New Broad Street, City, and had a large and select practice as a dentist, and attained a very high position in the scientific world. In 1836 he was appointed Professor of Zoology in King's College, London, when he ceased his lectures on Comparative Anatomy at Guy's. He was elected a Fellow of the Royal Society in 1828, and in 1848 was chosen secretary of that body, and held the office till his election as President of the Linnæan Society in 1853. Mr. Bell became an Honorary Fellow of the Royal College of Surgeons in 1844, and was formerly one of the Board of Examiners in dental surgery at the College. Besides numerous contributions to the Transactions and Proceedings of the Zoological and Linnæan Societies, he was the author of a work on the "Anatomy and Diseases of the Teeth," "History of British Quadrupeds," "History of British Reptiles," Gilbert White's "Natural History of Selborne," published in 1876. He gave up practice some years back, and retired to the Wakes at Selborne, Gilbert White's house, which he had purchased from the family of the naturalist, and where he died on the 13th inst., in the eighty-eighth year of his age.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on March 18th:—

Bartlett, Charles Richard, Halsey-street.
Clarke, William, Lamont, Ottawa, U.S.
Grindon, Francis James, Olney, Bucks.
Hepburn, John, Turnham-green.
Hormazdji, Robert Nesbit, Artesian-road.
Lecoq, Jules Arthur, Soho-square.

The following gentleman on the same day passed the Primary Professional Examination:—

Yeatman, John Walter, St. Bartholomew's Hosp.

COLLEGE OF PHYSICIANS IN IRELAND.—At the March examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Kyran Thomas Buggy, Charles Hayden Cox.
MIDWIFERY.—John Battersby, Kyran Thos. Buggy, Charles Hayden Cox, Arthur Richard Frederick Exham, Alexander Silcock.

SURGEON S. W. VASEY has been appointed to the *Seagull*.

THE Vestry of St. George's, Hanover-square, are about to undertake large works in wood-paving.

A FARMER of Street, Bridgwater, was fined £20 last week, at the Guildhall Police Court, for sending to market the carcases of sheep which had been suffering from fluke disease.

MR. FRANCIS WISE, of Cork, has presented £5000 to the Home for Protestant Incurables in that city. The Home requires about £3000 more to complete it, and, when finished, will, it is stated, be one of the finest institutions of the kind.

ADMIRALTY, March 23rd.—The undermentioned surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet, with seniority of this date:—Solomon Kellett, James D'Arcy Harvey, Thomas O'Sullivan, M.D., Joseph Wood, M.D.

HYDROPHOBIA.—An inquest was held on a woman at Hulme, Manchester, on Monday, and a verdict of "Death from hydrophobia" was returned. It appeared that the deceased was bitten on the thumb by an injured cat on January 27th. The wound, which bled profusely, was bound up, and healed. On March 16th, however, symptoms of hydrophobia supervened, and the woman died on the 18th.

BRISTOL CHILDREN'S HOSPITAL.—The annual meeting of this charity was held on the 20th inst., the Mayor presiding. During the past year 326 little ones had been received as in-patients, of whom 262 had been cured or materially relieved, 13 had died, and 88 were still under treatment; the out-patients had numbered in all (women and children) 3033. The total income for the year was £1262, but there remained an adverse balance of £54 14s. The system of requiring some payment from out-patients is still maintained. No note of introduction to the benefits of the hospital is required.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Miss Mary Woodward, of Sproughton, bequeathed £2000 to the East Suffolk and Ipswich Hospital, £1500 to the Essex Hall Asylum for Idiots at Colchester, £200 to the Essex and Colchester Hospital, £100 to the Suffolk Convalescent Hospital, and £50 to the Ipswich Lying-in Charity. Mr. Thomas Blackwell, of Soho-square, bequeathed £500 each to the Middlesex Hospital and the Westminster General Dispensary. The Brompton Hospital for Consumption has received £100 from "J. G. D." The Glasgow Royal Infirmary has received £100 under the will of Mr. Andrew Borland.

IRISH GRADUATES' ASSOCIATION.—The Irish Graduates' Association had their annual metropolitan dinner on St. Patrick's Day (Wednesday, 17th March), at the Holborn Restaurant, under the presidency of Mr. W. MacCormac, of St. Thomas's Hospital. Sixty-two members and guests sat down, and an excellent dinner was served. The following gentlemen were present:—Dr. Paget (president-elect), Dr. Balthazar Foster (treasurer), Drs. Daniell and Thompson (hon. secs.), Dr. Risdon Bennett, Mr. Wood, Mr. Erichsen, Mr. Jonathan Hutchinson, Dr. Greenhow, Mr. Mason, Dr. Ord, Dr. Milner Fothergill, Dr. Fancourt Barnes, Dr. Brodie Sewell, Dr. Tonge-Smith, Dr. Yeo, Rev. H. T. White, Dr. Wheeler, W. W. Mackeson, Q.C., Messrs. Wilson, Finlay, Mahr, Laistner, Wallace-Baines, H. Thompson, W. J. Frazer, Danaher, Vance, Wigmore, McBeath Davison, Butler, Croft-Oakes, Clements, Haddon, Hudson, Partridge, Murphy, Lough, Burton, McGrath, and many others. After dinner the usual list of toasts was given—"Our Rulers," "Our Guests," "Our Elders," "Ourselves." The latter was proposed by the President of the Royal College of Physicians of London in a very happy speech. The health of the President, Mr. MacCormac, was drunk with a bowl of Irish punch. A special selection of Irish music was played during dinner by the Holborn Band, and some exquisite violin and pianoforte recitals were given by Mr. Mahr and Mr. Laistner. Twenty-eight new members were elected. The company separated at a late hour, having passed a very pleasant evening.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

ABBOTT, G., M.R.C.S.E., L.R.C.P.L., has been appointed Surgeon to the Central London Ophthalmic Hospital, vice A. Dunnage, deceased.

BRIDGFORD, C. T., L.K.Q.C.P.I., has been appointed Medical Officer to the Bray Dispensary District, vice Whistler, resigned.

BURMAN, C. C., L.R.C.P.Ed., has been appointed Medical Officer to the Workhouse and West District of the Belford Union, vice Miller, resigned.

CHEYNE, W. W., F.R.C.S., has been appointed Assistant-Surgeon and Demonstrator of Anatomy to King's College Hospital, vice Yeo, resigned.

COLEMAN, H. W., L.R.C.P., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Upper and Lower Wootley District of the Bramley Poor-law Union.

DOYLE, C. W., M.B., C.M., has been appointed Medical Officer for the Fifth District of the Norwich Union.

FRAZER, A., M.D., has been appointed Medical Officer to the Drumkeeran District of the Manorhamilton Union, vice Nash, resigned.

GRAVES, T. W., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Glamorganshire and Monmouthshire Infirmary, Cardiff, vice Vachell, resigned.

KING, T., L.S.A.L., M.R.C.S.E., of St. Mary's Hospital, has been appointed Assistant House-Surgeon to the Female Department of the London Lock Hospital and Asylum, Westbourne-green.

KIRKMAN, J. M., L.R.C.P.Ed., has been appointed Medical Officer to Districts 1 and 2 of the Cricklade and Wootton-Bassett Union, vice Parker, resigned.

LLOYD, T. L., L.R.C.P., has been appointed Medical Officer for the Fifth District of the Drayton Union, vice Prior, resigned.

MACKENZIE, A. G., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Surgeon to the *Severn*, in the Royal Mail Steam Packet Company's Service.

MAUDSLEY, Mr. H., has been appointed House-Surgeon to University College Hospital, vice W. H. Neale, M.B., M.R.C.S.E., &c.

MURRAY, Mr. H. M., has been appointed Ophthalmic Assistant to University College Hospital, vice R. S. Walton, M.R.C.S.E.

PATERSON, W. H., M.D., C.M., L.M., has been appointed Medical Officer for the Spittlegate District of the Grantham Union.

ROSS, R. A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the First District of the Alderbury Union.

SHARPLES, W., M.R.C.S.E., L.S.A.L., has been appointed Resident Surgeon to the North Cambridgeshire Cottage Hospital, Wisbech, vice Pearse, resigned.

SHARMAN, Mr. P. E., has been appointed House-Surgeon to University College Hospital, vice W. Banks, M.R.C.S.E.

WHITE, J. R., M.B., L.R.C.S., has been appointed Medical Officer and Public Vaccinator to the Nos. 2 and 6 Districts of the Ongar Union.

WILLIAMS, D., M.B., B.Sc., has been appointed Physician's Assistant to University College Hospital, vice B. Pollard, M.R.C.S.E.

WOODHOUSE, W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the First District of the Norwich Union.

Births, Marriages, and Deaths.

BIRTHS.

RIDGE.—On the 19th inst., at Carlton House, Enfield, the wife of J. J. Ridge, M.D., of a son.

WINCKWORTH.—On the 16th inst., at Shefford, Beds, the wife of Charles Edward Winckworth, L.R.C.P.L. &c., of a daughter.

MARRIAGES.

BEHREND—WAGG.—On the 18th inst., at Bryanston-square (the residence of the bride's brother), Henry Behrend, M.R.C.P., of Norfolk-crescent, Hyde-park, to Marian, daughter of the late John Wagg, Esq., of Gloucester-place, Portman-square.

IRVINE—CORRIE.—On the 20th inst., at Fawley, Henley-on-Thames, Gerard James Irvine, Surgeon, Royal Navy, eldest surviving son of the late Gerard Irvine, Esq., M.D., of Bungalow, Irvinestown, County Fermanagh, Ireland, to Henrietta Frances Corrie, youngest daughter of the late William Byrom Corrie, Esq.

DEATHS.

MACKAY.—On the 17th inst., at Elphinstone-terrace, Hastings, Caroline Frances (Fannie), second daughter of the late George Mackay, M.D., R.N., Inspector-General of Hospitals and Fleets, and Honorary Surgeon to the Queen.

SYKES.—On the 17th inst., at Queen's-road, Dalston, of pneumonia, George Sykes, M.D., aged 49.

THOMSON.—On the 20th inst., at Berkeley-square, Bristol, Charles Edmunds Thomson, F.R.C.S., aged 73.

N.B.—*A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

SCIENCE TEACHING IN BOARD SCHOOLS.

AT a recent meeting of the Birmingham School Board (says the *Local Government Chronicle*) the Education Committee presented a report, recommending that a demonstrator be appointed, at a commencing salary of £250, for giving systematic elementary science teaching in the Board Schools. Following the plan which has been adopted by the Liverpool School Board, the Committee proposed that his duties should consist of—first, the organization of the instruction in elementary science in the schools, the performance of the experiments, and the giving of oral instruction to standards 4 and upwards of certain boys' and girls' schools; secondly, to teach classes of pupil-teachers to be established in connexion with the Science and Art Department, in the evenings or on Saturdays. The subjects to be taken will be, in the schools, mechanics for boys, and domestic economy for girls; and for the pupil-teachers (males) two or more of the following subjects:—Acoustics, light, heat, magnetism, and electricity; (females) animal physiology. The proposal was carried, after some discussion, by eight votes to five.

Volunteer.—The forage allowance for each horse in cavalry regiments is 12 lb. of hay, 10 lb. of oats, and 8 lb. of straw per diem.

BLEEDING IN PUERPERAL CONVULSIONS.

To the Editor of THE LANCET.

SIR,—A few days since I was called to see Mrs. Y——, who was expecting to be confined for the fourth time. She was about thirty years of age, of short build, thick neck, and florid complexion. At her first confinement she had convulsions; but at that time the os and soft parts were well dilated, and the attending doctor was able to turn and deliver a dead child, after which she only had two convulsions, but remained insensible for five days. When I saw her at this time she was in bed, complaining of severe pains in her head and slight ones in her back. On making an examination, I found the presentation normal, but the parts were not at all dilated. I gave her a mixture of chloral and bromide, ten grains of each, and she slept comfortably, but on waking complained that she could not see she had no true labour pains. She shortly went to sleep again, and awoke in a violent convulsion, with loud stertorous breathing, pupils insensible to light, and dilated. I made an examination, and found the os not dilated larger than a shilling, so it seemed impracticable to turn and deliver. Under these circumstances I sent for assistance, and administered chloroform to try and control the spasms, which I partly succeeded in doing till Dr. Shank, of Granville, arrived, which was probably in about three hours. We then bled in the arm, taking away an ordinary basinful of blood, and the spasms ceased, breathing becoming more natural, but pupils still insensible to light. I then applied a blister at the nape of the neck, and administered a powder of quinine and calomel. This was about five o'clock on the second day—i.e., I had been there since the previous evening at eleven o'clock. We continued to administer these powders at intervals of two hours, and at about half-past nine the child, a female, was born naturally, but was dead. A dose of castor oil was then given, and the bowels moved about eleven in the morning. I afterwards administered nitre and digitalis every three hours. The patient did not recover consciousness till twelve o'clock on the following night. She afterwards progressed as favourably as in any ordinary case.

What I wish to know is whether the treatment was correct, and whether anything else could have been done in the place of general bloodletting. Perhaps some gentleman who has had a similar case will kindly inform me in your columns how he treated it, and oblige,

Yours respectfully,

W. L. KING, M.D., L.R.C.S.C., &c.

Fredonia, Licking County, Ohio, March 1st, 1880.

STATISTICAL SOCIETY.

AT the usual monthly meeting on Tuesday, the 16th inst., Sir Rawson W. Rawson, C.B., K.C.M.G., in the chair, two papers were read: the first by Dr. T. Graham Balfour, F.R.S., "On Vital Statistics of Cavalry Horses," in which he showed that the subject has received much more attention in France than in this country. In 1843, owing to the heavy losses by glanders sustained by the army during the preceding ten years, a permanent Commission, presided over by the celebrated physiologist Magendie, was appointed, whose duty was to be the examination of all questions relating to the health and preservation of the horses of the army. The Commission established statistical returns to be furnished annually by the veterinary surgeons of the army, and was uthorised by the War Minister to publish an annual volume giving the results of these returns, and any information it might judge eserving of publication relating to the health of the horses. The rst of these reports was brought out in 1847, and twenty volumes had bee rpublished prior to the breaking out of the Franco-German war. The mortality of the horses in the French army during the thirty years 1837-66 averaged 58 per 1000 of the strength; ranging between 125 in 1841, and 26 in 1862; and the proportion "cast" was 80 per 1000, ranging between 135 in 1849, and 47 in 1855. The total loss amounted to nearly 14 per cent. annually. Dividing the thirty years into quinquennial periods, the mortality shows a marked progressive reduction, attributable to the improvements introduced by the Commission, the deaths in the last five years having been only 27·5 per 1000 as against 115 in the first. The reduction did not extend to the casting, which was higher in the last two than in the first two periods. The importance of these results is shown by the fact that a saving of upwards of £90,000 a year was effected in the amount required for the purchase of horses for the army during the last five years compared with what would have been necessary had the ratio of deaths and casting been the same as during the first five years. The influence of sex is shown in a slightly higher rate of mortality, but lower of casting among mares than horses. The mortality by ages shows the rate to decrease steadily till 11 years of age, when the minimum is reached. The casting, as might have been expected, increases steadily with advancing years. The disease which causes the highest rate of mortality is glanders, and next to it stands inflammation of the lungs and pleura. The highest death-rate by glanders occurs at the age of 6, after which it steadily decreases; the highest rate of deaths by lung disease is among the 4 year old horses. The chief cause of casting is legs worn out, which accounts for two-fifths of the whole. The mortality has been highest in the Engineer Train and Transport Corps, and lowest in the Imperial Guard, the latter being, in the opinion of the author, to a considerable extent owing to the Guard being mounted on better bred horses than the line. The admission of cases into the infirmaries averaged more than 50 per cent. annually, about one-fourth of them being on account of wounds and injuries. The influence of the seasons on the sickness is shown by a table of the admissions in each quarter of the year by the chief classes of diseases; they are lowest in the fourth, and highest in the second quarter. The returns, unfortunately, do not show the number constantly non-effective—a point of great importance. The information respecting the British Cavalry is very meagre. The deaths, on the average of eighteen years, 1861-78, were 21·07 per 1000, ranging between 16·9 in 1864, and 28·1 in 1871. The number cast averaged 98 per 1000, and ranged between 76 in 1871, and 156 in 1878. The mortality was lowest in the Household Cavalry, and highest in the Cavalry of the Line; while the casting was lowest in the Royal Engineers, and highest in the Military Train and Army Service Corps, the Household Cavalry furnishing the next highest proportion. There is no information available as to the causes of death and casting. The author concluded by calling attention to the very valuable results obtained by the statistical method of investigation as applied to the horses of the army in France, and suggested that a similar course should be followed in our service, more especially with a view to test the actual value, as a measure of efficiency and economy, of the importation into our cavalry of horses purchased in Hungary. He also pointed out the importance, as shown by the French returns, of stamping out glanders by killing all infected horses as soon as the nature of the disease is verified.

Mr. H. L. Harris.—The preparation (or something) may be procured of R. M'Cord, 1, Australian-avenue, E.C.

A LARGE CHILD.

To the Editor of THE LANCET.

SIR,—On the 15th instant Mrs. G——, aged thirty-five, wife of a butcher, was delivered of a fœtus which weighed 12½ lb. It was her ninth confinement, and she was assisted instrumentally. The circumference of the child's head was 12½ in.; chest, 19 in.; whilst in height it was found to be 23 in. The mother did well. This may be of some interest to your readers.

Yours &c.,

Manchester, March, 1880. P. I. L.

A PERIL AT HOME.

A DANGER which has more than once been pointed out was illustrated in the town of Thaxted, in Essex, a few days ago. A gentleman sitting in the coffee-room of an hotel observed smoke rising from the surface of the uncovered table on the side opposite to where he sat. The table was standing directly facing and under the front window, through which the sun's rays were passing at the time. On examining the spot whence the smoke rose, the surface of the wood was seen to be charred as by fire. A decanter filled with water was on the table in a direct line between the charred spot and the window. A piece of paper was laid on the spot after all trace of fire on the table was removed, and it immediately ignited. Lucifer matches were laid down with the same result. Thus the decanter of water appears to have acted as a lens to concentrate the sun's rays with a power sufficient to produce combustion.

Mr. Simeon Snell.—The paper will appear in an early number.

TOBACCO-SMOKING.

To the Editor of THE LANCET.

SIR,—In the discussion upon tobacco which has been going on in your pages lately, the question, as far as I have seen, has not been raised in connexion with the effect, if any, that smoking has upon the teeth. It has been usual, when the necessity arises for obtaining data upon a subject which is little known, to proceed at once to organise some statistics, and from these to draw a general conclusion; but obviously in the case before us, where so many causes are at work to produce the same result—namely, decay of the teeth,—any statistics drawn from those men who smoke and from those who do not would be of rather less value than statistics usually are. There is, however, one point which admits at any rate of some latitude for expressing an individual opinion, and that is whether or not tobacco-smoking augments the process of decay in a tooth in which decay has already commenced. A few observations upon this subject have inclined me to the belief that tobacco-smoking *has* this effect. Smoking may be innocuous to teeth already healthy; but let decay once appear, and its progress will be accelerated by the presence of the smoke. And to what may we assign the cause of this, assuming this suspicion to be correct? It seems to me that it is to be found in the chemical properties of the smoke—the combustion processes liberating from the tobacco the elements which are productive of the mischief. The irritating properties of tobacco-smoke are proved by the effect which follows its application to the conjunctiva. It is reasonable, therefore, to conclude that some such effect occurs upon the teeth in which decay has commenced. But how is it with a certain section of the community, one of whose pleasures in life is to chew tobacco? Judging only from what I have seen, I am bound to admit that, beyond blackening the teeth, it does not seem that the practice followed by these men is harmful as far as the teeth are concerned. I have looked into the mouths of many subjects upon the post-mortem table, the majority of them being seamen, whose propensity for chewing is well known, and frequently I have found the teeth sound and good, but, of course, intensely blackened.

Yours faithfully,

Paris, March 16th, 1880. M.R.C.S.

POST-MORTEM APPEARANCES IN A CASE OF STARVATION.

THE following description by Dr. Snowball of the appearances found thirty hours after death in a child five weeks old brought to the Children's Hospital, Melbourne, with a history of neglect and improper feeding, is given in the *Australian Medical Journal*:—"Brain pale, and of such thin consistence that on opening the dura mater it ran out like a pasty fluid. Lungs pale, but healthy. Heart: walls soft and flabby; no blood in cavities. Liver engorged with blood; gall-bladder *quite empty;* coats thin and pale. Coats of stomach and intestines greatly attenuated and pale; small quantity of fæces in lower gut. Kidneys pale, but healthy. All the internal fat absorbed."

Mr. T. L. Laen.—Cases are reported in THE LANCET of Feb. 15th and March 1st, 1873. We have no recollection of others.

SWELLING AND TENDERNESS OF THE LYMPHATIC GLANDS IN RÖTHELN (GERMAN MEASLES).

To the Editor of THE LANCET.

SIR,—I have been interested in Dr. Dyce Duckworth's account of rötheln in THE LANCET of the 13th inst., as, so far as I had noticed, he was the first English describer of the inflamed lymphatic glands that occur in the disease. In a considerable epidemic of the complaint that occurred here about seventeen years ago, this feature was not noticed, although in other respects the novelty of the complaint led to its being discussed one evening at our local Medical Society. During last year and this year the disease has revisited us, and now the tenderness and (moderate) swelling of the cervical and sub-occipital glands have been prominent characters, and yet not universally so, as in about one-fourth of the cases that I have seen they have not been detectable. A careful inquiry about the incubation has led to sixteen days being considered the usual period; but in some instances it has seemed to extend to eighteen, and in others even to twenty days.

I remain, Sir, yours &c.,

Brighton, March 15th, 1880. G. F. HODGSON.

ADVICE TO "A STRUGGLER."

A Struggler asks us how he can best introduce himself in a new neighbourhood, moving from an old one a little distance off, where he has achieved an income of £350 a year, including the proceeds of a district appointment; and he suggests the issue of circulars, intimating his change of address and his hours of consultation. Our correspondent says that he does not wish to do anything *infra dig.* Our advice would be not to do anything in the new neighbourhood and in the larger house, which would not even be dignified in the old neighbourhood, and certainly to leave the issue of circulars to the neighbouring tradesmen. The arrangements for utilising the larger house which our correspondent mentions are reasonable enough.

Mr. H. S. Reynolds should put his views into the form of an advertisement. He would probably soon find a purchaser for his practice.

FRACTURE OF SKULL; RECOVERY.

To the Editor of THE LANCET.

SIR,—I have the pleasure of forwarding to you notes of a case of rare and extraordinary injury to the skull without damage to the brain.

On October 17th, at 5 P.M., Manuel, a Portuguese boy, aged fifteen, was thrown from a horse, and dragged by the stirrup till his head struck against an iron pipe, when the strap parted. The horse ran off. The boy jumped up and started after him, but was caught and restrained by the bystanders. He was brought here immediately, quite sensible; clean-cut wound on right side of the head; a piece of skull, attached by a little bit of skin, hanging from the wound; wound five inches long, beginning an inch above the ear, running first straight up, and then backwards; dura mater apparently uninjured over a large uncovered space; slight bleeding only from the cut edges of the scalp. Some faintness, but no paralysis or other affection of the general or special senses. I attempted to replace the bone, but found it impossible. Skin brought together with sutures, and dressed with carbolised water. The patient had a good night, with very slight wandering of mind. The piece of skull was peeled, or rather dug out, clean off the dura mater. It is nearly a parallelogram, three and one-eighth inches from front to back, two and one-eighth vertically; very little periosteum on the outside; the inside masked by the groove of the middle meningeal artery.

Oct. 18th.—11 A.M.: Pulse 115; temperature 102°; complains only of soreness; mind quite clear.

19th.—Noon: Pulse 114; temperature 104°.

20th.—Noon: Pulse 120; temperature 104°. Wound dressed.

21st.—Noon; Pulse 125; temperature 107°. Wound dressed.

22nd.—Noon: Pulse 120; temperature 107°. Considerable suppuration; matter bogging below. I passed in a director, and made a counter-opening. Much pus evacuated.

23rd.—Pulse 122; temperature 101°. A strip of bare skull visible along the front edge of the wound; much discharge; erysipelatous swelling of right ear and face.

Till 26th.—Much the same; pulse 116; temperature 105°.

27th.—Pulse 84; temperature 100°. Still much discharge; swelling of face and ear has disappeared; night restless; appetite poor; can help himself in every way.

30th.—Noon: Pulse 97; temperature 103°; swelling appears in the upper lip and left ear.

31st.—Swelling in left ear alone; he is much stronger; pulse 96; temperature 101°.

Nov. 3rd.—Very little discharge; pulse and temperature normal.

4th.—Somewhat fallen off, though the appetite is now good; right ear has swollen again; pulse 88; temperature 105°.

5th.—Ear is well.

8th.—Doing well; pulse 85; temperature 100·5°. From this date he was well, except for the wound, which is now an inch and a half long, granulating healthily at the edge; almost no discharge. All the time the dressing has been carbolised water. He is very bright and happy.

16th.—A scale of bone came away, that which is noticed in report of Oct. 23rd.

24th.—Yesterday another scale of bone came away. To-day the granulations have closed over. The wound is nearly healed. The boy otherwise well.

Remarks.—The injury is a very remarkable one. It is hard to see how it could be artificially imitated. Could a good mechanic knock out a piece of skull, three by two inches, with clean rectangular edges, through a single cut in the scalp, under the condition that the brain is to suffer no injury? I am, Sir, yours faithfully,

ROBERT M'KIDDIE, M.R.C.S., &c.,
Surgeon to the Queen's Hospital.

Queen's Hospital, Honolulu, Jan. 12th, 1880.

MEDICAL CHARGES.

To the Editor of THE LANCET.

SIR,—As a general practitioner, my account for the attendance and service rendered, as detailed by "Extra-urban Practitioner," would have been delivered as follows:—"To medical attendance, July 20th to 24th inclusive, £2 2s."; and in my ledger a note thus: "Charge six visits, at 7s." Your obedient servant,

March 22nd, 1880. J. W.

P.S.—My practice is extra-*sub*urban, and among the class indicated my account is seldom or never questioned.

Traveller.—Our correspondent must be a much better judge of his question than we or any other person could be. There is no rule or tariff for such services. They should be the subject of an agreement beforehand. In any case the remuneration of the medical man should turn upon a number of social, financial, and professional considerations, of which no one but himself can be a judge.

IS JAGGARY AN ANTISCORBUTIC?

To the Editor of THE LANCET.

SIR,—Your last issue contains an anonymous communication under the above heading, offering some criticisms on my letter "On the Preventive and Remedial Effects of Molasses in Scurvy and Diseases connected with Chronic Starvation," which appeared in THE LANCET of the 31st of January last. To this communication it is difficult to reply in an edifying or useful manner. It is not necessary to occupy much of your space, but with your permission I will draw attention to the fallacy of a few of your correspondent's most prominent remarks.

The whole second paragraph, which occupies about half his letter, is devoted to commentaries on the causation of scurvy, which have so little bearing on the influence of jaggary or any other substance on that disease that I refer to it only to illustrate the illogical and incomprehensible manner in which he uses and draws inferences from my statements. After referring, in my letter, to the large experience of practical men as to the beneficial effects of molasses in scurvy on board ship, I proceed, by way of contrast and illustration, to say, in a general way, that the disease in India "was due to causes far removed from sea influences and salt provisions." Now, Sir, if "Famine Wallah" be not a disciple of Messieurs De Talleyrand and De Retz, who are credited with believing that the use of language is to conceal our thoughts, I submit that it surpasses the bounds of imagination how he can assume that I am a believer in what he is pleased to call "the exploded theory that scurvy is *per se* due to sea influence and salt provisions." The fact is, though I believe both, under certain circumstances, to be fruitful sources of scurvy, I am not aware that I have ever until now said so.

Again, your correspondent asks why do I say that the cattle died from want of salt? My answer is, because it is true; which, however, does not preclude the possibility of their dying from other causes. For example, if I assert that children die from small-pox, I have a right to expect that no sane person will run away with the idea that it is my belief that they may not also die from other diseases, such as measles or scarlatina.

His third paragraph concerns itself solely with a triple division of scurvy, which, as it is beside the question at issue, I have nothing to say.

In the fourth paragraph it is asserted, on what grounds I cannot imagine, that my experiments are advanced to prove "the preventive and remedial effects of jaggary in scurvy." With reference to this I have only to say that I made no experiments with such an object. My experiments were made with a view of testing the "powerful assimilation-assisting properties of jaggary," to which I have stated I attribute the greatest importance. I have not even hinted that the men experimented on suffered from scurvy. However, as he appears anxious to be informed "that if consonant with increase of weight I expect scorbutic symptoms to disappear," I say yes, at least in the vast majority of famine cases, and not only as regards scurvy, but most other diseases as well; and further, without such increase of weight, few indeed would remain long to be troubled with scurvy or other ills to which flesh is heir.

Now, Sir, one word as to the real question under discussion, and I have done. As I have been asked a large number of not very pertinent questions, and in not the most agreeable style, I should like in return to ask "A Madras Famine-Wallah" whether he has had any experience of molasses or jaggary either in his own case or that of others? For the present, at all events, as he has not brought forth any, I am forced to the contrary conclusion, and must therefore, however reluctantly, consider his opinions as practically worthless. Moreover, from the testimony of the New England ship captains as to the efficacy of molasses in scurvy, from the evidence adduced in its favour by Dr. Buzzard in "Reynolds's Medicine" during the civil war in America, where it was used with "decided benefit," and from my own experience and that of others in India, I have little hesitation in asserting that, had your correspondent performed the experiments he considers so conclusive, or given it a trial on himself, I am pretty confident he would not have been under the necessity of subscribing himself a "Famine-Wallah."

Yours faithfully,

Connaught-square, March 22nd, 1880. D. H. CULLIMORE.

RETRACTION OF THE TONGUE.

MR. H. MEYMOTT, of Ludlow, submits the following case as containing features of interest:—

William B——, aged twenty-five, labourer, had been suffering from bronchial irritation, and whilst at work on the 28th February suddenly lost all control over the muscular action of the tongue. I did not see him until several hours had elapsed. He could neither speak nor swallow. The tongue was much swollen, and he could not protrude it in the slightest degree. After several minutes' digital manipulation, and urging his own efforts to protrude it, I succeeded in bringing it out a little distance from the teeth, when it slipped back again. A second effort was more successful, and, to his immense relief, he could both speak and swallow. It remained in place, but was much swollen, and a large quantity of saliva was secreted. I gave him an astringent gargle, and he rapidly recovered.

Digitized by Google

Dr. Maurice G. Evans.—Mr. Keetley described an apparatus of the kind in THE LANCET for Jan. 8th, 1876. Or application may be made to the Secretary of the St. John's Ambulance Association.

Mr. R. S. Hudson.—The name will be inserted in the official list.

RARE CASE OF RETARDED LABOUR.

To the Editor of THE LANCET.

SIR,—The following case of retarded labour appears to me worthy of being placed on record :—

Mrs. W——, aged thirty-six, third confinement, who was delivered of twins in her previous labour, sent for me on October 28th, 1879, at 6.30 P.M. I found that she had been suffering slight pains since 8 A.M. that morning, when the waters had broken. I examined and found the os dilated to about the size of a shilling; had had no pains for more than an hour. I left her, and called again about 9 P.M., and found everything in the same state. I left, and she sent for me about 1 A.M. on the 29th, having had violent pains for about an hour. The os was now fully dilated, and the head descended slightly with every pain, but receded when it was over. Pains more or less violent every ten minutes. I waited for two or three hours, and then applied Simpson's long forceps, which slipped on my using some force. I reapplied them with the same result. I then obtained the assistance of Mr. Reckitt, who also tried the forceps with a similar result. Mr. R. then administered chloroform. I passed my hand into the uterus, and found the following condition of things :—A tight contraction of the internal os, or the lower fibres of the uterus, around the neck of the child, and compressing the cord, a loop of which had slipped down. The child, of course, was dead. I gradually inserted my hand further into the uterus and turned the child. I had some difficulty in extracting the head, which had been again grasped by the os internum, but eventually I overcame that difficulty by perforating, and so relieved my patient, who had been five or six hours in strong labour. She made a rapid recovery.

There is an account of a somewhat similar case read before the Edinburgh Obstetrical Society by Dr. Angus M'Donald, and published in the *Obstetrical Journal* for September, 1879. Dr. M'Donald remarked that his was an unusual case, there being very few recorded. I, therefore, thought this might be worth insertion.

I may add that had I known what was the cause of retardation, I should first have tried the effect of a full dose of opium; but when I had my hand in the uterus, I thought the wisest thing was to turn and deliver the woman, who was becoming exhausted.

Your obedient servant,

Newark-on-Trent, March, 1880. H. O. LUCAS, M.R.C.S.

Lumleian Lectures

ON

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.

Delivered before the Royal College of Physicians,

BY WM. ROBERTS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL MEDICINE TO THE OWENS COLLEGE.

LECTURE I.—PART I.

DIGESTION has been usually regarded as the special attribute of animals. They receive into their alimentary canal the food which they require for their sustenance in a crude form. It is there subjected to the action of certain ferments which transmute its elements, by a peculiar chemical process, into new forms which are fitted for absorption. Looked at in this restricted sense, plants have no digestive function. They possess no alimentary canal nor any vestige of a digestive apparatus. But when the matter is examined more profoundly it is seen that plants digest as well as animals, and that the process in both kingdoms of nature is fundamentally the same.

In order to understand this generalization—which was first propounded by Claude Bernard, and constitutes one of the most important fruits of his splendid labours[1]—it is necessary to recognise digestion under two types or conditions—namely, a digestion which takes place exteriorly at the surface of the organism, and a digestion which takes place interstitially in the interior of the organs and tissues.

Exterior digestion is that common process with which we are familiar as taking place in the alimentary canal of animals, by which the crude food introduced from without is prepared for absorption.

Interstitial digestion, on the other hand, is that more recondite process by which the reserves of food lodged in the interior of plants and animals are modified and made available for the purposes of nutrition.

These two types of digestion are essentially alike, both as regards the agents and the processes by which they are carried out; and although one type of digestion is more developed in the animal kingdom and the other type more developed in the vegetable kingdom, both types are represented in the two kingdoms, and bear witness to the fundamental unity of the nutritive operations in plants and animals.

I shall only be able to indicate in outline the facts and arguments on which Bernard sought to establish these propositions.

Exterior Digestion.

We all know that the alimentary canal is simply a prolongation of the external surface; that the skin is continued, at either extremity, without a break, into the alimentary mucous membrane. Accordingly the processes which take place in the digestive tube are, strictly speaking, as much outside the body as if they took place on the surface of the skin. Upon this inner surface, if I may so call it, are poured out the digestive juices, charged with the ferments which are the special agents of the digestive processes. This is the common condition of exterior digestion as it occurs in animals, but it is not the only condition. Among some of the lowest members of the animal series a permanent alimentary canal does not exist. In the amœba any portion of the exterior is adapted for the reception of food. The morsel sinks into a depression formed on the surface at the point of impact; it is digested in this improvised stomach, and the indigestible portions are expelled through an improvised anus.

Among plants exterior digestion is a much less prominent feature than among animals, but examples of its occurrence and evidence of its importance are not difficult to point out. In the lowest orders of plants-fungi and saprophytes, which are devoid of chlorophyll, exterior digestion is probably a function of prime necessity. In all likelihood their carbon-containing food is only absorbed after undergoing a process of true digestion. The transformation of cane-sugar by the yeast-plant is a striking example, though a distorted one, of exterior digestion. Cane-sugar is a crude form of food both to plants and animals, and requires to be transformed into invert-sugar (a mixture of equal parts of dextrose or grape-sugar and lævulose or fruit-sugar) before it can be made available for nutrition. The yeast-plant is no exception to this rule, and when placed in a solution of cane-sugar it is under the necessity of transforming that compound into invert-sugar before it can use it for its profit in fermentation. This transformation is effected by a soluble ferment attached to the yeast-cell, which can be dissolved from it by water. We shall see later on that a similar ferment exists for a similar purpose in the small intestine of animals, having the same property of changing cane-sugar into invert-sugar.

Even among the higher plants exterior digestion is not quite unknown. The function may be said to be foreshadowed in the excretion of an acid fluid by the rootlets of some plants which serves to dissolve and render absorbable the mineral matters in their vicinity. But genuine and most remarkable examples of this type of digestion occur among the so-called insectivorous plants, of which Mr. Darwin has given so interesting an account. In the sundews, the plant, by a peculiar mechanism provided on its foliage, seizes the insects which fortuitously alight on its leaves. A stomach is extemporised around the prey, into which is poured out a digestive fluid. The prey is digested, and the products absorbed, in essentially the same manner as in the gastric digestion of animals.

Interstitial Digestion.

Both animals and plants lay up reserves, or stores, of food in various parts of their tissues for contingent use, so that if you suddenly withdraw from them their food-supplies neither animal nor plant immediately dies—it lives for a certain time on its reserves. But before these reserves can be made available for the operations of nutrition they must first be converted from their inert and mostly insoluble state into a state of solution and adaptability to circulate in the nutritive fluid which constitutes the alimentary atmosphere of the protoplasmic elements. This conversion of inert store-food into available nutriment is brought about certainly in some, presumably in all cases, by the same agents and processes as the digestion which takes place in the alimentary canal of animals; and it is this identity in the agents and the processes which Bernard insisted on as the proof of the fundamental identity of the two kinds of digestion.

The storing up of food is carried on to a larger extent in the vegetable than in the animal kingdom, owing to the intermittent life of most plants. In their seeds, tubers, bulbs, and other receptacles are laid up stores of albumen, starch, cane-sugar and oil—designed primarily for the growth and nutrition of the plant or its offspring—but which are largely seized on by animals and utilised for their food. Owing to their more continuous life animals store up food less than plants. Nevertheless, they accumulate stores of fat in various parts of their body—of animal starch (glycogen) in their livers and elsewhere—and of albumen in their blood. Birds also store up large quantities of albumen and fat in their eggs.

The transformation of store food has been followed out most completely in regard to starch, its congener glycogen, and cane-sugar. Bernard worked out this subject with marvellous minuteness and success. It has long been known that the transformation of starch into sugar in germinating seeds was effected by diastase; and that a similar ferment, existing in saliva and pancreatic juice, performed the same office on the starchy food of animals. It has also been proved that the stores of starch laid up in the tuber of the potato and in various parts of other plants are changed at the periods of budding and growth in the same way and by the same agent. Bernard showed that animal starch or glycogen is stored up largely not only in the liver but in a variety of other situations, and especially that it is widely distributed and invariably present in large quantities in embryonic conditions. In juxtaposition with the glycogen is found a diastatic ferment which transforms it into grape-sugar, as it is required for the active operations of growth and nutrition.

The stores of cane-sugar which exist in the beet-root and

[1] Claude Bernard: Leçons sur les Phénomènes de la Vie. Tom. II. Edited after his death by Dastre. Paris, 1879.

Digitized by Google

in the sugar-cane are transformed or digested in like manner into invert-sugar when the plants enter on the second phase of their life—the phase of inflorescence and fructification. Here, again, it has been proved that the converting agent is a soluble ferment—the same ferment which, as already mentioned, is attached to the yeast-cell—and the same ferment which exists in the small intestine of animals for a similar purpose.

The transformation of store proteids and fats has not been followed out with the same success as that of starch and cane-sugar. But the evidence, as far as it goes, and analogy point to the conclusion that the stores of albuminous and oily matters contained in the seeds, bulbs, and other receptacles of vegetables are subjected to a digestive process before they are made available for the nutritive operations of the plants, and that the changes thus effected are of the same nature and are accomplished by the same agents as those which take place in the digestion of proteids and fats in the alimentary canals of animals.

I have, I think, said enough to show the scope of the evidence and the analogies from which Bernard deduced certain far-reaching generalisations, which I have ventured to summarise in my own language in the following propositions :—

(1) Digestion, or the process by which crude food is changed into available nutriment, is a function of capital importance in every form of active life. (2) This function is exercised partly on food brought into proximity with the surface of the organism (exterior, chiefly intestinal digestion) and partly on reserves of food laid up in the interior of the organism (interstitial digestion). (3) The agents concerned in this function and their mode of action are essentially the same whether the organism be a plant or an animal—and whether the action takes place in the interior of the tissues,—or on the general or intestinal surfaces.

General Characters and Properties of the Digestive Ferments.

The essential work of digestion is carried out by a remarkable group of agents, called soluble or unorganised ferments. These are found dissolved in the several digestive juices or secretions, which are thrown out on the path of the food as it travels along the alimentary canal. The physical and mechanical processes to which food is subjected in the mouth and stomach are all purely introductory, or preparatory, and are solely intended to facilitate the essential work of digestion, which consists in the action of the digestive ferments on the alimentary principles.

The number of distinct ferments employed in the digestion of the miscellaneous food used by man is not accurately known, but there are at least seven or eight of them. The accompanying table presents in one view a scheme of the several digestive secretions or juices—and the ferments which they contain—together with an indication of the action of each ferment on the several alimentary principles.

Table of the Digestive Juices and their Ferments.

Digestive Juices.	Ferments contained in them.	Action on Food Materials.
Saliva	Salivary diastase or ptyalin	Changes starch into sugar and dextrine.
Gastric juice ..	*a.* Pepsin	Changes proteids into peptones in an acid medium.
	b. Curdling ferment	Curdles the casein of milk.
Pancreatic juice..	*a.* Trypsin	Changes proteids into peptones in alkaline and neutral media.
	b. Curdling ferment	Curdles the casein of milk.
	c. Pancreat. diastase	Changes starch into sugar and dextrine.
	d. Emulsive ferment	Emulsifies and partially saponifies fats.
Bile	?	Assists in emulsifying fats.
Intestinal juice ..	*a.* Invertin	Changes cane-sugar into invert-sugar.
	b. ? Curdling ferment	Curdles the casein of milk.

An examination of the table shows that a long and complicated series of ferment-actions is required to accomplish the digestion of our food. Starch is attacked at two points—in the mouth and in the duodenum—by two ferments, salivary and pancreatic diastase, which are substantially identical. Albuminous matters are also attacked at two points—in the stomach and in the small intestine; but here the two ferments, pepsin and trypsin, are certainly not identical. The ferment, of which the only known characteristic is to curdle milk, is found in the stomach and in the pancreas—and I think also in the small intestine. The bile is not known to possess any true ferment-action, but it assists, by its alkalescent reaction and by its physical properties, in emulsifying and promoting the absorption of fatty matters. The ferment which transforms cane-sugar, strange to say, is not encountered until the food reaches the small intestine.

The known digestive ferments all belong to the class of soluble or unorganised ferments. They are sharply distinguished from the insoluble or organised ferments, of which the type is yeast, in not having the power of self-nutrition and self-multiplication. All living organisms possess this power either in a dormant (potential) or in an active (kinetic) state. Soluble ferments cannot therefore be said to be alive—but they are exclusively associated with living organisms and take an essential part in their vital operations.

The digestive ferments are all the direct products of living cells, and may be regarded as detached repositories of cell-force. They are quite unknown in the domain of ordinary chemistry. Their mode of action bears no resemblance to that of ordinary chemical affinity, and has a distinctively physiological character. They do not derive their marvellous endowments from their material substance. They give nothing material to, and take nothing material from, the substance acted on. The albuminoid matter which constitutes their mass is evidently no more than the material substratum of a special kind of energy—just as the steel of a magnet is the material substratum of the magnetic energy—but is not itself that energy. This albuminoid matter of the ferment may be said to become charged, at the moment of elaboration by the gland-cells, with potential energy of a special kind—in the same way that a piece of steel becomes charged with magnetism by contact with a pre-existing magnet. The potential energy of the ferment is changed into the active form (i.e. becomes kinetic) when it is brought into contact with the alimentary substance on which it is designed to act.

The chemical and physical characters of the digestive ferments appear to be tolerably uniform. In composition they resemble proteid substances, and contain carbon, oxygen, hydrogen, and nitrogen in the same or somewhat similar centesimal proportions as albumen. But as not one of them has yet been obtained in a state of absolute isolation and purity, this is, strictly speaking, a matter of inference rather than an ascertained fact. They are all soluble in water; they are all diffusible, though with difficulty, through animal membranes and parchment paper. They are also capable (all those I have tried) of passing through porous earthenware by filtration under pressure; but some of them pass through readily, and others with the utmost difficulty and only in the smallest proportions. They are precipitated from their watery solutions by absolute alcohol; but, unlike other proteids (peptones excepted), they are not truly coagulated by alcohol. When the alcohol is removed, the ferments are still found to be soluble in water and to retain their activity unimpaired. They are coagulated and rendered permanently inert by the heat of boiling water; and when in solution they are coagulated and destroyed by a heat of about 160° Fahr. (71° C.)

Each digestive ferment has its special correlative alimentary principle, or group of principles, on which alone it is capable of acting. Diastase acts exclusively on amylaceous substances. Pepsin and trypsin act only on the azotised principles; the emulsive ferment of the pancreas is only capable of acting on fatty bodies; the inversive ferment of the small intestine has no activity except on cane-sugar.

The changes impressed on alimentary principles by the digestive ferments are not, chemically speaking, of a profound character; and they affect much more the physical state of these principles than their chemical composition. In the main they are processes of deduplication and hydration; and the result is to render the substances operated on more soluble and more diffusible—to diminish their colloidal state, and to make them approach, or even to reach, the crystalloid state. This does not appear to be an invariable event, however. Cane-sugar is a marked exception—it is converted in the small intestine into invert-sugar (a mixture of equal parts of grape-sugar or dextrose and fruit-sugar or lævulose); but invert-sugar, though more highly hydrated than cane-sugar, is neither more diffusible nor more soluble.

It does not appear to be absolutely true that all food

Digitized by Google

requires digestion before it can be absorbed. Fat is largely taken up by the lacteals in its unaltered state, except in so far that it is finely divided or emulsified. Grape-sugar (dextrose) is not known to suffer any digestive operation, but to be absorbed unchanged. Perhaps it would be more correct to say that grape-sugar is an article of food predigested for us by the agency of plants.

Although the mode of action of digestive ferments is special and peculiar, the results of that action are not peculiar, but can be obtained in other ways by ordinary chemical forces. By long-continued boiling in water—and more rapidly by boiling with acidulated water—starch is converted into dextrine and sugar, and albumen is changed into a substance resembling peptone. The peculiarity of the action of ferments consists in this: that the ferments are able swiftly and without violence to produce changes which by ordinary chemical agencies can only be produced either by strong reagents, or by long-continued and very slow action of weaker reagents. It is interesting to remark that the changes produced in food by digestion are, in their ultimate results, very similar to, if not identical with, those produced by protracted cooking.

The Preparation of Artificial Digestive Juices.

The study of the digestive ferments has been immensely facilitated by a method first introduced by Eberle. Eberle discovered that an aqueous infusion or extract of the digestive glands possessed the same properties as the natural secretions or juices of those glands. The reason of this is that the glands which secrete the digestive juices contain within them a reserve stock of their respective ferments. Accordingly when the glands are infused in water their reserve stock of ferments passes into solution. These infusions or extracts then constitute artificial digestive juices which operate in a flask or beaker in the same way as the corresponding glandular secretions act in the alimentary canal. Solutions of organic matters are, however, extremely perishable—they pass quickly into putrefaction. In order to obviate this inconvenience, and to obtain an extract which is always handy for use, various preservative means have been employed. Bernard used carbolic acid—others have used glycerine or common salt. These preservatives, although perfect for the purpose intended, have a pronounced taste which is impossible to get rid of. I have made a good number of experiments on this point. As the ultimate object I had in view was to obtain a solution which could be administered as a medicine by the mouth—or which could be employed in the preparation of artificially-digested food—I sought for a preservative which either had little taste and smell, or one which was volatile and could be got rid of by vaporization. After a good many trials I adopted the three following solutions as on the whole the best suited for the purpose.

1. *Boracic Solution.*

This solution contains 3 or 4 per cent. of a mixture of two parts of boracic acid and one part of borax. An extract of the stomach or of the pancreas made with this solution keeps perfectly, and has little taste and no smell. For experimental purposes, this extract is, I believe, all that can be desired—it is neutral in reaction and is chemically inert. It answers well also for administration by the mouth when the dose does not exceed one or two teaspoonfuls. But when larger quantities are required for the preparation of artificially-digested food, and when food thus prepared has to be used day after day in quantity sufficient to sustain nutrition, larger quantities of boracic acid and borax are taken into the stomach than that organ can always comfortably tolerate.

2. *Dilute Spirit.*

The second solution is water mixed with 12 or 15 per cent. of rectified spirit. This solution makes a most excellent extracting medium, and the quantity of spirit in it is so small as rarely to be an objection to its use. In the preparation of artificially-digested food a final boiling is usually requisite, and in this final boiling the alcohol is dissipated. On the whole, this is perhaps the most generally useful of the three solutions.

3. *Chloroform Water.*

Chloroform dissolves in water in the proportion of about 1 in 200; these are the proportions employed in the preparation of the *Aqua Chloroformi* of the British Pharmacopœia. This forms a perfect solvent for the digestive ferments, and its keeping qualities are unrivalled. But though the quantity of chloroform dissolved is so minute (about two and a half drops in a fluid ounce), it communicates a somewhat powerful smell and taste to the solution. This taste and smell are agreeable to most persons, but not to all. It is, however, quite easy to get rid of the chloroform. If the dose to be used be first poured into a wine-glass or saucer and left exposed to the air for three or four hours, the chloroform passes off almost entirely in vapour, and leaves behind a simple aqueous solution of the ferments. Or if the solution is employed for the preparation of artificially-digested food, the chloroform, being very volatile, disappears in the final boiling. It is perhaps well to mention that chloroform water has the property of reducing Fehling's solution, and that this property has to be taken into account in making experiments on digestion which involve testing for sugar.

Alimentary substances fall naturally into three well-marked groups—namely, *Carbohydrates*, *Proteids*, and *Fats*. I propose to consider the digestion of the three groups in the order here indicated. I have, however, no intention of dealing systematically with these subjects, but rather to take up certain points and questions in regard to which I have myself made observations, or which have a bearing on the preparation of artificially-digested food and its administration to patients. I shall treat the digestive transformation of starch in some detail, because this has been worked out almost to completeness, and because it probably furnishes a type which will hereafter be of service as a guide to the study of the more complex problem of the digestion of proteids.

THE

Gulstonian Lectures

ON

EPILEPSY.

Delivered before the Royal College of Physicians,

BY W. R. GOWERS, M.D., F.R.C.P.,

SENIOR ASSISTANT-PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE III.—PART II.

THE last question is, What is the nature of the tissue change? Can we form any opinion as to the character of the alteration in the grey matter which permits its sudden, explosive discharge? This problem is essentially the same, whatever theory of epilepsy is adopted. The violent muscular contractions suggest a corresponding overaction of the nerve cells, and it has seemed to some, as Dr. Hughlings Jackson, that such repeated overaction can hardly be other than an indication of increased functional activity—of increased, if abnormal, nutrition. On the other hand, others, and foremost among them is Dr. Radcliffe, have maintained that the general conditions of epileptics and the phenomena of epilepsy suggest impairment of functional power, and that a symptom so abnormal as an epileptic fit can hardly result from normal nutrition, to whatever excess it may be carried.

Modern physiology teaches us, I think, in what direction an answer is to be sought. It is necessary, in the first place, to avoid too direct an inference from the outward manifestation to the internal process. No one probably now imagines that the nerve-force, which sets a muscle into action, forms part of the force liberated by the muscle; and, although the two are no doubt proportioned, the difference between them may be as great as between the energy liberated by an electrical spark and by a charge of gunpowder which it fires. We may easily overrate the amount of nerve-force needed to cause violent muscular action, and may also overrate the relation which the nerve-force bears to the potential energy of the cells concerned.

Every nerve-cell may be described as a storehouse of latent energy, and may be compared by analogy to a charged

Digitized by Google

Leyden jar, or, what is more convenient for our present purpose, to a bent spring. The energy of the spring is due to the force which has bent it, and depends on the resistance which keeps it bent. The recognition of the resistance to action in nerve-cells, and of the part which it plays in normal processes, is a most important step in modern physiological thought. Of the nature of the resistance we can form perhaps no idea, but its existence in nerve-cells may be taken as hardly needing proof, for we are unable to conceive of their action without it, and the idea has underlain such expressions as "nerve tension," and the like, which have been long employed. The fact is probably only the highest instance of a series of relations which runs through the whole of organic nature. The formation of every organic compound, for instance, consists in, so to speak, the bending back of the spring of chemical affinity in a process by which force is held latent by some unknown resistance.

The application of this mode of thought to the morbid action of the nervous system promises to yield clearer views of many problems of disease, and for this step we are chiefly indebted to some important and suggestive papers by Dr. Ringer. The state of a nerve-cell, whether at rest or action, may be regarded as depending on the proportion which its tendency to liberate energy bears to the resistance within it. The action of a nerve-cell may depend on the production of force within it being increased, in excess of the resistance, or on the resistance being unduly lessened. The cessation of its action may depend on the tendency to liberate energy being diminished, or on the resistance being increased. It is highly probable that all the phenomena of "inhibition" depend on increase of resistance by the action of one cell upon another. It is, indeed, conceivable that the interaction of the nerve-cells of the brain may be such that their mutual influence is a balanced resistance, and the amount of force in the brain, nascent but restrained, may be infinitely greater than any manifestations of energy which we perceive could possibly suggest. We may, perhaps, ultimately learn to regard the effect of stimuli in developing nerve-action, not after the analogy of the mechanism of a piano, each blow upon a key directly exciting the sound, but rather after that of an organ, in which the movement of a key merely lessens the resistance to the action of a pent-up force.

Do not, I would ask, the phenomena of epilepsy best accord with the theory that the unstable equilibrium of grey matter depends on instability of resistance rather than on any primary change in the energy-producing action of the cells? When loss of blood develops general convulsions, by its action on an otherwise healthy nerve-centre, can we conceive, I would ask, as Dr. Radcliffe has asked before, that it acts by increasing the production of nerve-force? It appears far more intelligible to regard its effect as a sudden diminution of resistance, by which the pent-up nerve-force is suddenly released, the nascent energy developed. The arrest by the ligature of fits which begin deliberately seems to point in the same direction. A strong peripheral impression causes such a change in the grey matter to which the discharge is advancing, that the discharge is arrested there, and passes no further. We can hardly conceive the effect of the impression except as causing a local increase of resistance, so that the liberation of energy ceases at the spot, can no longer occur. Once arrested in this way it is arrested for a considerable time. If the discharge depended on a primary increase in the energy-producing action of the cells, we should expect it to recur when the ligature was removed. It does not. I have a patient who has, for a long time, arrested every fit, commencing in the hand, by a ligature above the elbow. At first, if he did not apply the ligature, the attack went on into a general convulsion. He now finds that the sensation, beginning as before, stops, of its own accord, at the spot at which the ligature used to be applied, and never goes on to a fit. According to the view I have suggested, the repeated increase of resistance has led to a corresponding permanent change, resting on an alteration of nutrition, so that the unstable grey matter is limited by a zone of greater stability, where the discharge is arrested.[1]

Analogy suggests that the internal resistance to action is a higher function of the nerve-cells than the mere transformation of energy. The control is a higher function than the production of the force. Hence the fact that there is an apparent overaction becomes consistent with the theory that there is imperfect nutrition.

The discussion of the real nature of these influences—the liberation of energy, and the resistance to action—how far they are ultimately to be referred to vital, chemical, or electrical changes, is beyond the scope of these lectures. The recognition of one point only appears to me essential—that nutritive changes may underlie them, and that from them nutritive changes may result.

Two other points in pathology remain for mention. I have suggested that failure in resistance, permitting the liberation of energy, constitutes the essential element in discharge, and that such discharge causes the symptoms of the epileptic paroxysm. Physiological considerations make it probable that the resistance in cells may be raised and lowered by the action of cells at a distance. There are a few phenomena of minor attacks of epilepsy which seem best explicable by assuming that the resistance in a centre is suddenly raised (perhaps by the action of other cells) instead of being lowered. A patient, for instance, whose severe fits affect one side only, may have slight attacks which consist only of sudden transient weakness in the side. We have seen that while visual sensations, due hypothetically to discharges in the visual centres, are frequent warnings, sudden inability to see may also be part of an aura, and such inability to see must be regarded as a sudden inhibition of the visual centre, that is, a sudden increase of resistance within it. A slight increase of resistance affords the best explanation of the apparent diminution in the size of objects. The increase of resistance is equivalent to a diminution in the sensitiveness of the centre, and the effect upon it of the stimulation of a given area of the retina is less than normal, and corresponds to the effect of a similar stimulation of a smaller retinal area. The object appears smaller and farther off, and as the resistance in the centre increases, the object may appear to recede. It is the opposite process to that which occurs in lessened resistance in the centre. This commonly results in such liberation of energy as affects consciousness. There is a visual impression, perhaps a sense of a ball of fire; and as the discharge spreads this seems to get larger and larger. The effect is the same as if an increasingly large area of the retina were stimulated. There is one centre which is usually inhibited, rather than discharged, in epilepsy—the centre for the motor processes of speech.

The phenomena of hystero-epilepsy seem to point to an instability of grey matter of different seat and perhaps different kind. The excessive violence of the muscular spasm in that disease is comparable only to the convulsions of epilepsy and tetanus. The phenomena appear due to the more deliberate and sustained overaction of centres which are concerned in specialised, co-ordinated movements, in emotions, and also in intellectual processes. The fact that some patients in these attacks fall suddenly, and remain still for a few moments before the co-ordinated movements commence, has been regarded by Dr. Hughlings Jackson (adopting a theory of the late Dr. Dickson) as evidence that the "co-ordinated" phenomena are always due to the release of lower centres from the control of the higher by the temporary discharge of the latter. He has urged that an actual discharge of grey matter can only give rise to inco-ordinate "brutal" effects. That co-ordinated convulsive action may succeed attacks of true epilepsy is beyond all question; but it is also, I think, beyond question that the co-ordinated phenomena are not always preceded by epileptic symptoms. In some cases which I have watched the attacks commenced with the co-ordinated movements which characterised them throughout. The tonic rigidity, which initiates the attacks in other cases, cannot be regarded as a true epileptic symptom; it is rather part of the hystero-epileptic attack, and may recur during its course. Thus I think that there is in many cases no evidence of true epileptic symptoms, that the co-ordinated convulsion, which constitutes the chief symptom of the hystero-epileptic attack, may exist alone.

Even for the cases in which this symptom succeeds a true epileptic seizure, it may be doubted whether the hypothesis of "loss of control" affords an entirely adequate explanation. We can discern no difference between epileptiform attacks which are, and those which are not, followed by such symptoms. This suggests that this occurrence depends

[1] That variations in tissue-resistance may influence the *spread* of a discharge which has already commenced has been recognised by Dr. Hughlings Jackson. (Brit. Med. Jour., Jan. 11th, 1879.)

Digitized by Google

upon some other condition, a condition pertaining to the nervous organisation of the individual and not to the form of attack. This is supported by the fact that cases in which epileptic attacks are succeeded by "co-ordinated convulsions" present (as we saw in the first lecture) distinct characteristics in age, sex, causation, and conditions under which the fit occurs. In these respects they resemble the patients in whom such attacks of hysteroid character occur without any preceding epileptoid symptoms. These facts make it probable that there is in these epileptics, in addition to the instability of nerve-tissue which causes epilepsy, also the instability, whatever it may be, which gives rise to hysteroid attacks. "Loss of control" may be the immediate mechanism by which this instability is thrown into operation, but will not alone account for its existence, and is no necessary condition for its manifestation. Nevertheless, in some patients the hysteroid tendency may be so slight that it never manifests itself spontaneously—never except during the post-epileptic state. Hence I think that the old conclusion is the true one; that all patients who present these co-ordinated convulsions after epileptic attacks are really the subjects of both epilepsy and hysteria. The existence of the epileptic symptoms may be obvious, or may be most difficult to detect; initial simple tonic spasm cannot be regarded as evidence of their existence, and it may be practically impossible to say, in many cases, without the rare opportunity of witnessing the onset of the attacks, whether there is or is not an initial truly epileptiform seizure. This is the explanation of a point in the method of these lectures which may have occasioned surprise; while endeavouring to distinguish the two diseases, I have not ventured to separate them. Such a separation I believe to be practically impossible; to attempt it would entail an error, the amount of which would be unknown, and certainly large. I have therefore considered each fact with regard to the entire series; endeavouring to ascertain, however, the extent to which it is true of the cases with, and those without hystero-epileptic, or co-ordinated convulsion. The former term, "hystero-epileptic," has been employed in its popular meaning, without reference to theory, as a designation for the severer forms of hysteroid attack, in which their violence, severity, and recurrence bring them practically nearer to the disease which we call epilepsy than to that which we designate hysteria. I cannot but think that it would be a gain if we were to discard the dubious word "hysteria," even in its modifications, as a designation for such attacks, and call them simply "co-ordinated convulsions."

Such forms of attack, in which the convulsive phenomena are violent in degree and disorderly in sequence, are in the lowest grade of co-ordinated phenomena, while the highest are those forms of involuntary action which we call automatic. In these, complex actions are performed, sometimes with considerable skill, of which the patient is subsequently entirely unconscious. Dr. Hughlings Jackson has long maintained that these are really post-epileptic phenomena. That they are commonly such, all must, I think, agree. The older view was that these were true epileptic events, the result of such changes in the brain as might, in another degree or part, constitute an ordinary epileptic attack. While recognising that they are commonly post-epileptic, I doubt whether the older view must be entirely discarded. Many of the phenomena mentioned in the first lecture may make us hesitate to assent to the conclusion that the discharge of epilepsy must always cause inco-ordinate symptoms. What, for instance, is the vision of an old woman making ugly faces, which one patient had sometimes as the aura of a fit, sometimes as an attack of *petit mal*, but an automatic action of—a co-ordinated discharge in—the centre for visual ideas? The remarkable aura which I detailed at length suggests the same explanation, and so do many others that were alluded to. I have seen a patient suddenly, while being watched, without the slightest pallor, hesitation, or any symptom to indicate a discharge in the highest centre, proceed to empty his pockets, take off his coat, or to some action which in him characterised and I think constituted his attacks of minor epilepsy. With regard to the attacks of post-epileptic automatism, the same difficulties face us as in the case of the co-ordinated convulsion. We have the facts that in one individual attacks may always be followed by automatic action; and in another, similar attacks may never be so followed. This suggests that there is, underlying the phenomenon, a condition of the centres on which it depends. Were it not for this condition the epileptic attack would not lead to it, and this condition may, in rare cases, cause its primary manifestation.

Lectures
ON SOME
RECENT INVESTIGATIONS
INTO THE
PATHOLOGY OF INFECTIVE AND CONTAGIOUS DISEASES.

Delivered in connexion with the Brown Institution, at the University of London, Dec. 1879,

BY W. S. GREENFIELD, M.D. LOND., F.R.C.P.,
PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTION, ASSISTANT-PHYSICIAN AND LECTURER ON PATHOLOGICAL ANATOMY TO ST. THOMAS'S HOSPITAL.

LECTURE I.—PART III.

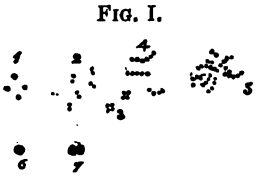
I MAY now proceed briefly to describe these several genera of bacteria, limiting myself to the forms which may be observed in a pathological connexion, though not necessarily as the causes or results of disease.

Micrococci: Spherical Bacteria. — The simplest forms of bacteria are the spherical or globular bacteria—micrococci. Various names have been given to these: thus one variety has been called *microsporon* by Klebs; and there are other names applied to various groupings of these bodies. They are distinguished from rod-shaped bacteria by their globular or ovoid form. According to Cohn, they are cells, colourless or slightly coloured, which multiply by transverse fission into moniliform filaments consisting of two or more members, so as to form a chain (torula-form); or else into large colonies or balls; or into masses consisting of innumerable members massed together, with but little intercellular substance, which are variously called glœa, zooglœa (Cohn), or mycoderma (Pasteur). According to Cohn they are motionless. Individual micrococci are usually less than one micromillimetre ($1\mu = \frac{1}{25000}$ in.) in diameter, their size of course varying with the different species, and also to some extent with their nutrition.

Many different terms are used to designate the various forms which the elementary spherules produce by their arrangement—such as chain-form, rosary-form, dumb-bell-form, sarcina-form, and the like. But it is much better to discard these terms, together with names like "leptothrix" and "vibrio," which have no special meaning, merely indicating forms which may be assumed by very different organisms.

The form in which micrococci are usually met with and most readily distinguished in decomposing animal fluids, or in the living fluids of the body under pathological conditions, is that usually called double or dumb-bell micrococci. They have then the appearance of two minute, highly refractile spherules closely joined together; this, in fact, representing an organism in course of division; but such is the activity of reproductive fission that it is the condition in which they commonly appear. This form is represented in Fig. I., 2 and 7; the simple elementary spheres being seen at 1

FIG. I.



and 6. Doubtless an explanation of this fact is that before complete separation occurs between the two members of a divided micrococcus the process of fission in the separating members has already commenced, so that they are rarely seen as isolated spheres. When, however, they grow more slowly in a tissue or in a quiescent fluid, they may form

Digitized by Google

chains, single or in groups, as at 4 and 5 (Fig. I.), or sarcina-like groups of four, as at 3—the latter more rarely; and they have also an especial tendency to grow into globular masses composed of an infinite number of densely aggregated individuals.

Whether as isolated double elements, or in zoogloea masses, many micrococci stain very readily and deeply with various reagents, and not unfrequently of peculiarly vivid colour, this fact, as we shall see, being of especial value in the study of their relations to disease.

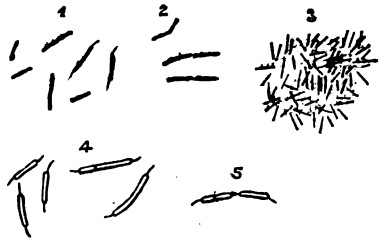
Having mentioned that, according to Cohn, micrococci are motionless, I must add that they very commonly appear to be in very active movement, and that this movement does not always appear, judging by ordinary criteria, to be a mere Brownian movement. It is, I believe, very probably due to the active nutritive and molecular changes which they are undergoing in the course of their rapid growth and fission.

Micrococci are met with in nearly all infective fluids, and, indeed, in all decomposing animal fluids at certain stages. In the lymph of vaccinia, and some other contagious fluids, micrococci are also constantly present. I shall mention later some of the views which have been entertained as to their significance in these fluids; here I may say that whilst some have divided micrococci into zymogenic or fermentation-producing, chromogenic or colour-forming, and pathogenic or disease-causing, attempts have also been made to attribute to these bodies the *rôle* of contagia, and thus the micrococcus vaccinæ, micrococcus diphtheriticus, and many others have been described. For all these it must be said that the term *pathogenic* should not be used, unless it can be shown that these bodies are not merely constantly present, but that they are the actual causes of the disease; a point to be further considered.

Can micrococci alter their form and become further developed into rod-shaped bacteria, or do rod-shaped bacteria divide into micrococci? These questions are as yet only incompletely solved. Billroth is one of the chief authorities in favour of the view that micrococcus and bacterium are two forms of the same organism. Klebs alleges that he has seen bacteria divide into micrococci. Dr. Cossar Ewart states that he has seen bacterium termo elongate and form numerous spores, which escape and form swarms, which, if separate, would be indistinguishable from micrococci.[1] Like many others, I believe it to be highly probable, for many reasons, that micrococci may be spores of rod bacteria, but I have not been able to prove it experimentally. I have grown micrococci in successive generations under varying conditions, but without ever producing a single rod bacterium, and so has Professor Ewart. Amongst the facts which indicate it as probable that some micrococci are the spores of some rod bacteria is the fact that rod bacteria often contain nuclei closely resembling those of bacilli, and these very possibly hold a similar relation to them. Another fact is that in cultivating the spores from a bacillus and watching them through various generations, I have found that sometimes they pass into a condition in which they continued to multiply, but from which I was unable to reproduce the bacillus.

Bacteria proper; Rod-shaped Bacteria.—The second genus, bacterium proper, includes several varieties, of which the most important for our purpose is the common bacterium

FIG. II.



1 and 2, Rods of bacterium termo. 4, The same under higher power, showing flagella (these should be longer and the bodies shorter). 5, Rod dividing. 3, Part of zoogloea mass under a lower power.

termo of decomposition. Rod-shaped bacteria consist of short rods which multiply by transverse fission, not forming long chains, but, according to Cohn, only four members at the most being seen in a line. These rods are usually in active movement, having, however, alternate stages of rest and motion at different periods of their existence. In the motile stage they possess flagella, usually one at each extremity, and in all probability this is true of all the forms which possess the power of movement at any stage, though as yet only proved with regard to a few species. In the case of bacterium termo, the flagella were, I believe, first described by Dallinger and Drysdale,[2] and they have since been observed by others. The extreme difficulty in observing them may be judged from the fact that the average length of bacterium termo, as estimated by Dallinger, is only 2·5 μ, or $\frac{1}{10000}$ inch; the diameter of the body ·8 μ; whilst the diameter of the flagellum is only ·08 μ, or about $\frac{1}{100000}$ of an inch. If, however, a fluid containing bacterium termo in active growth be watched, one may often see during the process of fission that a rod becomes attached to the cover-slip, then divides, and the parts separate; but the free rod, which is in more active movement, struggles for some time before it becomes detached, and every movement is attended by a corresponding motion of the fixed rod, showing that though at a distance, the two are still attached by an invisible link, resolved by higher powers into the thread-like flagella.

When bacteria are cultivated they grow into zoogloea masses, in which is a definite permanent intercellular substance, formed, according to Cohn, by the partial solution of their envelope. The formation of spores in bacterium termo has been observed to occur in two ways. Dr. Ewart (*loc. cit.*) states that he has seen them growing into long rods, in which spherical spores developed at short intervals. These, after two or three days, became free, and lay isolated or formed a zoogloea, subsequently germinating into short rods. The individual spores themselves closely resembled micrococci, but did not, like them, undergo subsequent division. The other form in which spores are observed consists in the presence of a single nucleus-like body at the end of a short rod—a condition not uncommonly seen in putrescent fluids.

It will thus be seen that there are many analogies between the changes occurring in these bacteria and those to be described in bacilli. Bacterium termo comprises members having considerable differences in size and length; the latter usually varies from 2 to 4·5 μ. Their especial pathological interest has reference to their constant occurrence in the course of putrefaction, and the experimental researches in the production of sepsin by their action.

3. *Filamentous Bacteria (Faden-bacterien); Bacilli.*—It is in relation to this group, which may be regarded as practically coextensive with bacilli, that the most important discoveries of recent years have been made. And, as there seems to be a sort of glamour about the very name "bacillus," it seems desirable that I should dwell upon the group with some detail.

Bacilli were originally defined by Cohn as consisting of elongated cylindrical parts, which when isolated are similar to bacterium lineola, and multiply by transverse fission; but which also form long chains composed of similar rods, at the junction of which no constrictions are seen. Cohn stated that they often form swarms, but never true zoogloea masses. They, like bacterium termo and lineola, have alternate stages of rest and motion. The facts thus stated by Cohn represent important features of bacilli, but there are many others of no less importance. For we now know that bacilli go through a number of stages of development, and assume various conditions, the formation of spores being one of the most important. In short, bacillus rods may elongate and divide into a number of rods, or assume the shape of long filaments in which spores develop. Again, these spores may become free and escape from the filaments, or the filament may break up into segments corresponding to the spores; the spores may form swarms or remain isolated; and they may, previous to regeneration of the filaments, themselves undergo subdivision. In describing these changes more minutely I shall divide the genus bacillus into two groups, and shall take as types of each bacilli which I have myself observed.

The first class presents a transition stage from bacterium termo, and it may be a question whether further observation will show its greater analogy with that class, or whether it is a merely accidental variation in mode of growth. It is a class in which the rods, after multiplication, do not form long convoluted filaments, but arrange themselves in heaps,

[1] M. Dallinger has, I believe, recently stated that he has watched the transition of one into the other form, but I have not seen the paper.

[2] Jour. Roy. Microsc. Soc., 1878. Vol. i., p. 169.

not unlike the zoogloea of bacterium termo. I have been able to watch the growth of only one bacillus of this kind; it appears to be identical with one described by Dr. Koch, as occurring under similar conditions. This was an extremely minute bacillus found in a form of septicæmia in the guinea-pig, and represented in Figs. 3, 4, and 5. The bacillus as seen in its simplest condition is a slender rod, as at Fig. III. 1. Sometimes two are joined end to end, as at Fig. III. 2. These rods under cultivation elongate into filaments from six to eight times the length of the original

FIG. III.

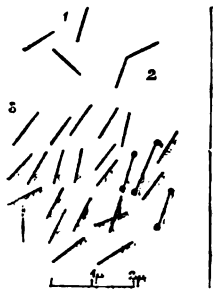

FIG. IV.

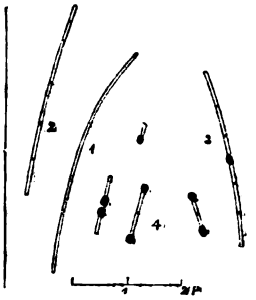

FIG. III.—Bacillus from a form of septicæmia in the guinea-pig (semi-diagrammatic). 1, Straight rods. 2, Two rods joined together, forming a bent rod. 3, Group of rods, some with spores, after cultivation.

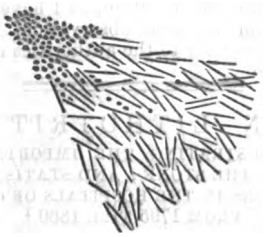
rod, and either break up into shorter rods, as at Fig. IV. 2, or remain homogeneous (Fig. IV. 1). In these rods spore-formation takes place, either in the free rod, as in Fig. IV., or in the zoogloea masses, as at Fig. V. The growth of these zoogloea masses is a matter of some interest. If a cultivation be watched it will be found that rounded masses develop, which, on examination, consist of short rods densely massed together, towards the outer part radially arranged, and in the centre often appearing to consist almost entirely of spores (possibly partly due to rods seen endwise). A segment of such a mass somewhat diagrammatically represented is seen in Fig. V. If the individual

FIG. V.



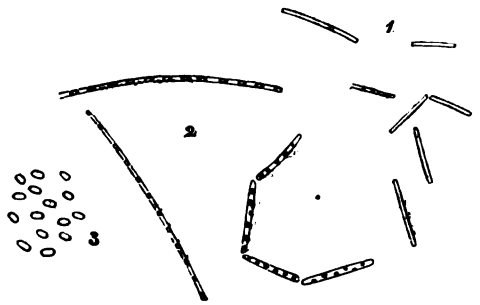
Segment of a circular zoogloea mass, composed of rods and spores.

elements are studied with a higher power, as at Fig. IV. 4, there will be found rods with two spores together in the centre, rods with terminal spores, some in course of division, and short rods with one spore at or near the end. These elements are identical in shape with those seen in other bacilli, and on these and other grounds I have agreed with Koch in including them in that class.[3]

The second class, that better known, consists of the group of bacilli which comprises bacillus anthracis. What I shall have to say with regard to the changes seen in bacillus anthracis holds good for the most part of several other bacilli. A bacillus, which I shall be able to show you in several stages, grown from the serous fluid of a "farcy bud," the bacillus of hay infusion described by Cohn, a bacillus shown by Timothy Lewis to develop in the blood of some healthy animals after death, the bacillus of pneumo-enteritis of swine discovered by Klein, the bacillus malariæ of Klebs, and probably many others, different in size, habitat, and pathological relations, varying also in some particulars, yet all follow much the same general course of growth under cultivation. These changes we may now study with the aid of Figs. VI. to X., most of which are from drawings of bacillus anthracis.

The bacillus rods, as seen in the blood (Fig. VI., 1), are

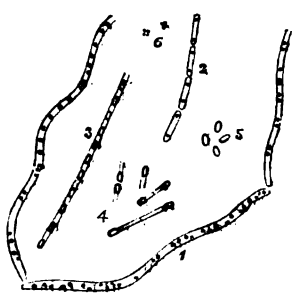
FIG. VI.



Bacillus anthracis. 1, Rods as seen in the blood, viewed with magnifying power of about 450 diameters, and enlarged to double the size of original drawing. 2, Rods formed in cultivation, magnified 500 diameters, enlarged. 3, Group of spores. (Semi-diagrammatic.)

long and slender, almost homogeneous or slightly granular in appearance. Frequently they are more or less curved or bent; they may be longer and jointed, in this case being made up of several segments in course of separation. In the animal body they usually multiply by elongation and transverse fission, and probably only in this way under the common conditions. But when artificially cultivated, and also under certain favourable conditions in the body during life or after death, a different course of multiplication is observed. The rods elongate to an enormous length, and form dense masses of filaments, which curve in various directions, sometimes forming spirals or loops, at others lying in parallel bundles, or various other arrangements. Sometimes also they merely form bundles of shorter parallel rods, the bundles often crossing each other obliquely. In the filaments thus formed various changes may ensue, which may be considered separately as modes of fission and modes of spore formation. The filaments may break up into short or long segments previously to spore formation, as at 1 and 2, Fig. VII., and 1, 3, and 4, Fig. IX.

FIG. VII.



Bacillus from farcy-bud. 1, Curving filaments, showing irregular granules, many situated laterally. 2, Filament breaking up into short rods, at the ends of which are commencing spores. 3, Filament with regularly arranged spores. 4, Parts of filament after breaking up. 5, Spores. 6, Sporules. (These are drawn too small. See Fig. X.)

More commonly spore formation occurs previously to complete fission, and the spores escape from the filaments, or the latter break up into spore-containing segments.

The mode of formation of spores can readily be watched in the bacillus anthracis, owing to its relatively large size. In Fig. IX. I have drawn a number of these stages, as seen in a recent cultivation. The filament or rod consists, as we know, of a delicate sheath, enclosing granular protoplasm. In the ordinary rod condition the separation of the two is often made out only with difficulty. When cultivated the central protoplasm becomes more distinct at certain points, and aggregates itself into masses, either uniformly or at irregular inter-

[3] To avoid further reference, I may say that this particular bacillus is a still one, so far as I have seen. I was able to cultivate it through seven successive generations. Its extreme minuteness makes its study a matter of extreme difficulty; the stages represented in Fig. IV. were only seen with 1-25th inch and very careful illumination. The measurements are, for the same reason, only approximative, and the figures are diagrammatic enlargements of my original sketches.

Digitized by Google

vals, the spaces between becoming clear, and some indication of commencing segmentation of the filament also appearing. In the granular protoplasm there now appear bright, highly-refractile, oily-looking points, which increase in size, and

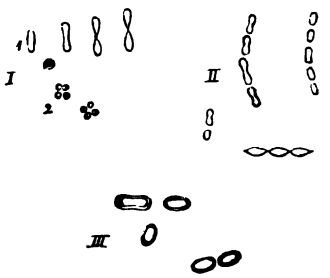
(In the woodcut the space between the sheath of the filament and its contents is necessarily represented somewhat too wide. In 5 there was no visible separation between the two in the original drawing. The ends of the rods and of the protoplasmic contents should be more blunt, less rounded.)

form the spores. Sometimes the entire protoplasmic mass seems to be absorbed by the spore, at others a portion remains surrounding it. It is not uncommon to see the first sign of spore-formation at the sides of the filament, as in 1, Fig. VII. This has been made a ground of distinction of bacillus malariæ, but I have seen lateral spore-formation in two other kinds of bacilli. When formed, the spores may be arranged pretty close together or at regular and nearly equal intervals, or in pairs, or sometimes scattered more irregularly. (See Figs. VI., VII., VIII., and IX.) The spores may now become free by escape from the rod, and remain isolated, or form swarms, as at 3, Fig. VI. Or, again, the filament may waste, the spores remaining *in situ*, as at 8, Fig. VIII., or it may break up into pieces, each containing a spore near or at the end, as in Fig. VII. 4, and Fig. VIII. 9.

The spores thus formed are, in the case of bacillus anthracis, oblong bodies, very highly refractile, and, when examined under a very high power, seem to have an outer hyaline sheath (Fig. X. iii.) If kept under conditions favourable to slow germination, they are apt again to subdivide into smaller bodies (*Sporules*, Ewart). This change is seen in Fig. X. The spore elongates, becomes hour-glass-shaped, then divides, each segment again dividing laterally, so that a group of four, sarcina-like, is formed. This change was, I believe, first described by Ewart as occurring in bacillus anthracis; I have myself repeatedly observed it in the same, and also in the bacillus from farcy. I agree with Dr. Ewart that it is not a degenerative change, for the fluid from which the organisms in Fig. X. were drawn was used to inoculate a sheep with fatal effect, and I have been able to trace growth of bacillus rods from these sporules; as has Ewart also.

FIG. X.



Old cultivation of bacillus anthracis, containing spores in course of division. I. Stages of division. 1, Elongation and constriction in centre. 2, Sarcina-like groups of sporules. II. Rows of spores (probably remains of filament), some undergoing division. III. Spores and sporules more highly magnified.

Of the growth of the spores into bacillus rods I must say but little. Unquestionably they do grow into rods, for if a minute quantity of fluid containing no visible microscopic elements but spores be cultivated, rods are reproduced, and if the spores alone of bacillus anthracis are inoculated in a living animal, they reproduce the typical disease with enormous development of rods in the blood. But the precise mode of growth has been disputed. Some say that the central protoplasm of the spore elongates into the rods, bursting the capsule; others that the capsule also elongates; whilst others insist that the capsule, or remains of the filament, grow into the rod, the spore proper remaining unchanged. My own observations lead me to believe that the spore as a whole elongates into the rod, but I do not venture to offer a decided opinion.

I have thus sketched some of the more important morphological changes. The importance of the spore-formation, and of the division of the spores into sporules, become especially apparent when we have to deal with their durability, and their relations to disease. I have not described the flagella which exist in some forms—they need only be mentioned here.

I shall say nothing of spirillum, as I have not any facts to state derived from my own observation. For these and other details I may refer to the authorities already quoted.

ON LITHOTRITY;

WITH CASES ILLUSTRATING THE IMPORTANCE OF EARLY DETECTION OF THE STONE; AND STATISTICS OF STONE OPERATIONS IN THE HOSPITALS OF GLASGOW FROM 1795 TILL 1880.[1]

BY GEORGE BUCHANAN,

PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF GLASGOW.

THIS communication contains little that is new except the statistics of the Glasgow hospitals. The arguments in favour of lithotrity have been presented in nearly identical terms in many papers and treatises which have appeared in recent years; nevertheless I think that this is one of the subjects which should be brought before the profession periodically, as experience increases, say at intervals of ten or twenty years.

In 1859 I compiled, for the late Professor Lawrie, a statistical table of the operations in the Glasgow Royal Infirmary. The statistics were published in the *Glasgow Medical Journal* for April, 1859. In 1868 I read before this Society a paper on lithotrity, and in it gave the results of the operations contained in the records of the Royal Infirmary till that date. In the present communication I shall give the statistics of all the operations for stone performed in the hospitals of Glasgow, from the opening of the Royal Infirmary in 1795 and the Western Infirmary in 1874, till 1st January, 1880.

[1] Read before the Glasgow Medico-Chirurgical Society.

Digitized by Google

The bringing forward of these figures, however, I intend to make the occasion for a few remarks on the operations for calculus; which indeed are but the reiteration of what has been said by Civiale, Sir B. Brodie, Sir W. Fergusson, Dr. Prout, Sir Henry Thompson, Mr. Coulson, and others, and in the various Systems of Surgery. Still, a profession constantly changing as ours is, by the addition of junior members, ought to have brought before it, from time to time, subjects admitting of discussion as this does, especially when the experience of later years is gradually substituting one operation for another, which was universal at a comparatively recent period.

The most recent conclusions arrived at may be best expressed in two propositions.

1. It is of the utmost importance that the presence of a calculus in the bladder should be ascertained before it has reached any considerable size; and as a corollary the bladder should always be explored with a sound, on the occurrence of the earliest symptom.

2. All small and moderate-sized calculi may be removed by the lithotrite, and, as a consequence, when this doctrine is accepted and carried into practice, lithotomy will gradually be abandoned, except in cases of an exceptional nature as regards the stone and patient.

On each of these propositions I shall make a few remarks.

First: the early detection of the stone. This is the key to the whole position. Of course it is true of all diseases that the sooner they are detected and their nature proved the better both for patient and surgeon. But it is true in a different sense for calculus, because it may make the difference between a nearly perfectly safe operation of lithotrity and a very dangerous one of lithotomy or lithotrity.

Let me recall for a moment the prominent symptoms.

(*a*) Pain in the perineum or the region of the base of the bladder, often accompanied by pain in the point of the penis. But pain is often altogether absent in early stages of calculus, and frequently present in cases of bladder disease in which there is no calculus; as in two cases under my care just now in which the patients describe the suffering at the orifice of the urethra as most acute.

(*b*) Frequent desire to pass urine. This is an accompaniment of irritation of the bladder from whatever cause, but being present, is a sufficient reason of itself to warrant a careful search for a stone.

(*c*) The presence of blood, either in the urine or coming in a few drops after urine has been passed. This also is present in many bladder and urethral affections, even in the second form mentioned.

(*d*) Interference with the continuity of the flow of urine—i.e., either partial or total interruption of the stream, which recommences after a short interval or by change of position.

(*e*) Easily observable changes in the urine, as in colour, clearness or rather muddiness, thickness, viscidity, odour, &c., which are often remarked by the patient himself, and are the cause of his consulting his medical attendant without any of the other symptoms referred to. These are the evidences of chronic cystitis, which is more often idiopathic than the consequence of stone, but in many examples are the only symptoms to indicate the presence of a stone.

Now, with regard to these five symptoms which I have enumerated, I presume that if any patient came under medical treatment with them all present, there are few if any medical men who would not at once suggest that an exploration of the bladder should be made at the very first. But I am not so sure that it would be recognised as a general principle, that so soon as a patient presents any one or even two of them, the exploration should be made.

It is generally believed that stone in the bladder is not so common in this country as it was fifty years ago, and if that is true the necessity of searching for it is, numerically, not so imperative as formerly, still it is sufficiently common to make it important to have it in view in presence of the symptoms referred to. I shall have something to say in a subsequent part of this paper with regard to statistics of stone, but with reference to its frequency I may here state that since 1858, the date of my first lithotomy, I have had eighty cases of calculus in the bladder besides a few in the urethra.

Now I can assert that while in most of the cases which have come under my notice, two or more of the symptoms were present, yet in several instances only one of them attracted notice and continued the sole evidence for a considerable period, till the introduction of the sound proved the presence of a stone. And what I think ought to be recognised as a principle in all urinary disorders is, that as soon as one of the known symptoms of stone is discovered, the bladder should be explored by a sound. The manipulation scarcely ever gives any annoyance if performed with a properly constructed sound and a gentle hand, and the information obtained, positive or negative, is of the utmost importance. If the calculus is very small it may elude detection at a first examination, so that if the symptoms either continue or recur the sounding should be repeated. By this means a stone could be discovered before it has grown larger than a garden bean, and if the practice referred to were generally adopted, few stones would ever come to be dealt with of a size to be seen in all collections at the present day, except where from gross neglect on the part of the patient the symptoms were concealed and endured till increasing suffering drove the patient for advice.

I think the importance of searching for stone on the occurrence of *one* of the first four symptoms alluded to—that is, before there are any symptoms of cystitis, which is almost always accompanied by alkalinity of the urine—is rendered evident by a knowledge of the intimate structure of calculi; for an examination of any considerable collection of calculi shows that in the vast majority of examples the nucleus of a calculus is uric acid or oxalate of lime, and that a phosphatic calculus is a very rare thing. When such a phosphatic stone does exist, it consists in almost every instance of an aggregation of smaller pieces held together by inspissated mucus, or which have become adherent to one another first by mutual pressure and then by consolidation of the intervening substance. Such calculi are somewhat porous, like pumice-stone. When in 1874 I removed my pathological collection to a room provided for me in the Western Infirmary, Dr. Foulis (at that time my house-surgeon), undertook to arrange and catalogue the preparations; and before arranging the calculi I got every one of them sawn through the centre, and thus exposed the internal as well as the external structure. And the examination of these sections convinced me of the almost universal prevalence of a nucleus of oxalates or urates, whatever the external shell of the stone might be. Dr. Foulis informs me that since he has been appointed the pathologist of the Royal Infirmary, he has examined the specimens there in a similar way with the same results. This corresponds with what has been found in the examination of all collections in which the calculi have been divided, so as to expose their internal structure. But in many collections this has not been done so uniformly as to make the observations complete.

Now, as oxalate and urate calculi are hard and presumably of slow growth compared with phosphatic, it follows that in the history of all calculi or nearly all, there is a time, and a considerable time, when they are small, hard, and of slow growth, and that is just the time when their presence may be indicated by the symptoms—pain, desire to micturate, blood, interference with the flow—occurring either singly or at considerable intervals, with intervening periods of total cessation of these symptoms, so as to throw the patient and even the medical adviser off their guard. And this is true to some degree even of the small number of calculi which are phosphatic from their first origin.

I think, then, we may conclude that if only the patient would apply on the first occurrence of anything unusual connected with his urine or the region of the bladder, and the medical attendant would have the bladder at once explored, calculi would be detected when of very small size, in almost all instances.

2. The second proposition I would bring forward is that all small and moderate-sized calculi may be removed with almost perfect certainty of a favourable result by lithotrity. This general statement must indeed be modified by the circumstances of each case, involving the condition of the patient and the nature of the stone. But I may state the case as follows: Given an adult in fair health, with a normal urethra, the bladder not too irritable, and containing a calculus not larger than a filbert,—any surgeon using the lithotrite with ordinary care may with confidence undertake to remove the stone by lithotrity with very little anxiety as to the result. But in the case of lithotomy it is different, as all practical surgeons know. There is anxiety as to the result even after an operation performed with dexterity and success, so far as the manipulation is concerned. Sir William Fergusson's words on this subject cannot be too thoughtfully considered—"There seems to me to be a mystery associated with lithotomy which has not yet been solved. For palpable

Digitized by Google

errors there is an explanation; but when to all appearance there has been perfection in the operation, and yet death has been the issue, I confess I have been puzzled beyond measure." Again: "Working on inanimate material, no doubt precise manipulation must be of the most perfect effect; but when the phenomena of life are involved, the result seems in most instances beyond human control." I think every one who has had much experience of lithotomy will corroborate Sir William Fergusson's words.

I do not think that numerical results founded on the experience of any one in Scotland, as yet, will do much to help my argument; nor are the aggregate results as obtained from statistics of the Scottish hospitals sufficiently extensive to authorise any valid conclusion; still the experience of individual cases will often bias an operator in a way which is both intelligible and justifiable.

My first intimate connexion with lithotrity was in the case of a gentleman who in 1861, when sixty-four years of age, was cut for stone by Mr. Syme, who extracted two uric acid calculi. In 1864 a recurrence took place, so that in 1865 he had a stone removed by lithotrity by Sir Henry Thompson. In 1867 it again recurred, and I removed it by lithotrity in a fortnight, and from that time till his death in 1872 he continued perfectly free from all trouble in connexion with urination. Now a comparison of the pain and discomfort which he suffered after lithotomy with the relatively little annoyance while undergoing lithotrity, made a most powerful impression on me in favour of the latter. Previous to this operation I had done my first lithotrity on a patient in the Royal Infirmary, in July, 1866, with success. There are several gentlemen well up in years, from whom I have removed calculi by lithotrity with very little trouble or annoyance to them, now in perfect health; on whom, I confess, I would have performed lithotomy with very great anxiety and fear for the result. So that my own opinion is strongly in favour of lithotrity in favourable cases, and certainly always in the case of stones of small size.

(To be concluded.)

THE DIAGNOSIS OF TUMOURS OF THE CEREBELLUM.[1]

BY STEPHEN MACKENZIE, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN TO, AND LECTURER ON PATHOLOGY AT, THE LONDON HOSPITAL.

BEFORE speaking of the symptoms which enable us to diagnose tumour of the cerebellum, it will be convenient to describe three cases which illustrate these symptoms, and in which post-mortem examination verified the diagnosis.

CASE 1.—J. G——, aged two years and eight months. Previous to the age of two years walked, and was quick in intellect. When seen for the first time, August 3rd, 1876, by Mr. Garrett, the clinical assistant at the London Hospital, it was elicited that the first symptoms noticed were staring of the eyes and stiffness of the neck. When these symptoms had lasted about two months, vomiting occurred, and the child became feverish and sleepy. She was said to have oxyurides. On August 31st double optic neuritis was observed. The child was constantly moaning, but was not then sick. I saw the patient on Sept. 4th, and found her wasted, moaning, and fretful. The head was large, and extremely retracted, and it could not be bent forward. There was well-marked double optic neuritis in an acute stage. Owing to the extreme retraction of the head, there was constant gurgling in the throat from bending and stretching of the trachea. When she swallowed liquids her mother said they came back through her nose. Her head had been persistently retracted about a week; previous to that she had leaned it upon her right hand. She had attacks in which she became quite stiff. There was no paralysis of the bladder. No affection of the sight had been observed when she was brought to the hospital. She could shut her eyes when told to do so. From the presence of double optic neuritis I inferred intracranial tumour. The enlargement and retraction of the head, and the history of tetanic seizures, led me to diagnose without hesitation tumour of the cerebellum. There was no index as to its nature. The case had been regarded as one of meningitis. I suggested the administration of iodide of potassium. She was seen on Sept. 7th and 14th, and her condition was practically the same. She resisted attempts to draw her head forward by putting up her hands. On the 14th there was doubtful drooping of the right eyelid. She died on the 16th. One week before her death she had two partial fits, in which "she went stiff, and turned up her eyes and her lips."

The necropsy was made ten hours after death by Mr. Garrett. The ventricles of the brain, including the fourth, were distended with fluid. The cerebellum was adherent to the occipital bone. On its inferior surface was an irregular flattened tumour spread out beneath both lateral lobes, and compressing antero-posteriorly the middle lobe.

Microscopical examination showed the tumour to be a myxomatous glioma.

CASE 2.—A. D——, aged three years and three months at time of death. Always thin and somewhat delicate. The child "always had a dreadful look in the eyes; they were beautiful but sunken and dark." When twelve months old, in climbing over the door-board, he fell, striking his head. It was thought from the direction in which he fell that he struck his head in the frontal region. He appeared to have no ill-effects from the fall, either at the time or subsequently. Was thought to have consumptive bowels when six months old, and at this time had some head symptoms. When a year and a half old he had a fit. "He lay quite stiff and firm, as if he was dead." He was so stiff that his father said, "It was no use getting a bath for him." He lay in the fit about twenty minutes, and it was followed at first by cerebral excitement, and afterwards by stupor and temporary strabismus. Three months later he had whooping-cough very badly, and the cough did not leave him for twelve months. His walking was not so good after the whooping-cough, and he used to sit down a good deal. He quickly lost the use of his legs. He did not reel nor stagger, or at least not much. He was brought to me at the London Hospital November 17th, 1877. He was then a well-nourished child with a large head. He was unable to stand. He was irritable and screamed a good deal. His head had not been observed to be enlarged when he was brought to the hospital, but after this was pointed out to the mother she tried on his caps and found them all too small, and he could only just wear his father's. Ophthalmoscopic examination showed the presence of double optic neuritis. The enlargement of the head, the loss of power in the lower extremities, and the history of convulsive seizures of a tetanic character led me to suspect a tumour of the cerebellum, involving probably the middle lobe. At subsequent visits the observations were confirmed, and the diagnosis made with greater confidence. In January, 1878, he had a fit, in which the left arm and right leg were quite stiff, the right arm and left leg being much less so. Soon after this the left arm was noticed to be weak, so that he never used it. Expedients were tried to induce him to do so, but he was tremulous with it. From this time he drooped more. His head was now so heavy that he could not raise it, and he always lay with the right side on the pillow. In February he had numerous convulsive attacks (indeed, almost whenever he was moved), in which his legs became stiffened and straight, with the toes turned in. From this time his dejections were passed under him; he had previously been continent. In July I noted the head had continued to enlarge greatly; it was 22½ in. in circumference at the centre of the forehead. The anterior fontanelle was widely opened. The enlargement of the head was chiefly at the back part, behind the ears. There was still lymph on the discs. From this time till his death in January, 1879, all his symptoms deepened. His head continued to enlarge; he became quite blind; he had frequent attacks in which all his extremities became quite rigid, the legs being extended, with the feet turned in, the arms being rigid and pronated to the utmost, or at other times (especially at an earlier period) flexed. He became affected with thrush, but it did not appear to add to his distress. For two or three months he took no notice of anything, did not open his mouth for food, did not cry or smile, but moaned. For the last three weeks "he took no food whatever." If fluids were placed in his mouth, they lay there without his making any attempts at swallowing. He now wasted rapidly. For the last three or four days he

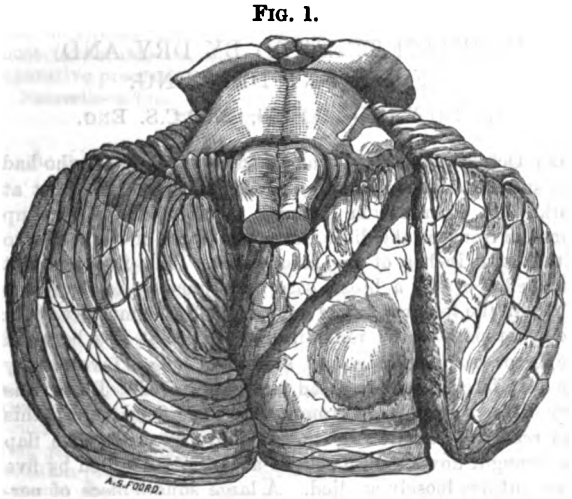
[1] Read before the Hunterian Society, Nov. 26th, 1879.

Digitized by Google

lay on his left side, his arms perfectly rigid, either pronated or supinated to the utmost. The fingers were extended to such a degree that his mother says, "No person could (voluntarily) put his hand into such a position." The legs were rigid, and perfectly extended. His eyes at times rolled up, at others were naturally directed. His head was drawn back occasionally, but not to an extreme degree.

Necropsy day following death.—Head greatly enlarged, measuring 23½ inches in circumference, 7¾ inches in antero-posterior axis, and 6¾ inches at the widest lateral diameter, behind the ears. Enlargement of head not quite symmetrical on two sides. Anterior and posterior fontanelles open over a space about the size of a shilling piece. Coronal and occipito-parietal sutures gaping, the bones nowhere meeting. The sagittal suture yielded slightly, but less so than the others. Fontanelles depressed, eyeballs sunken in orbits, features natural. Calvaria extremely thin—a mere shell, semi-translucent. Dura adherent to calvaria. Pia natural. Brain removed entire with great difficulty, owing to its fluid contents. Convolutions much flattened and almost translucent; tremulous from the fluid in ventricles. Infundibulum distended; when cut into about three pints (measured) of clear fluid escaped from the ventricles, and the brain collapsed into a flattened mass. The hemispheres were not thicker than a quarter of an inch. The lateral ventricles were enormously dilated, measuring almost six inches in the long diameter. They formed two large, almost spherical sacs. The other ventricles were all enormously dilated; the iter a tertio ad quartam ventriculum admitted a finger. In the floor of the left lateral ventricle was an irregular nodular mass of yellowish-green colour, with smaller excrescences, projecting into the ventricle from about the situation of the corpus striatum. The smaller nodules on the surface were white or whitish yellow. When cut into the mass was of a yellowish-green colour, and of about the consistence of cheese. When the posterior cerebral lobes were displaced the cerebellum was observed to be unsymmetrical, the left lobe projecting higher than the right. The left and middle lobes felt very dense. On turning the lower surface upwards there was found to be a large mass occupying the middle and left lobes, covered with membrane somewhat thickened and irregular, and attached to the occipital bone. When the tumour was cut into it was found to be a dense caseous mass of greenish-yellow colour, breaking down in a few places into irregular cavities. The tumour was quite as large as a full-sized billiard ball. The medulla oblongata was much flattened in its antero-posterior direction, so as to be almost riband-like. (Fig. 1.) The thoracic and abdominal organs

FIG. 1.



Showing tumour involving middle and left lobe of cerebellum, and compressing medulla.

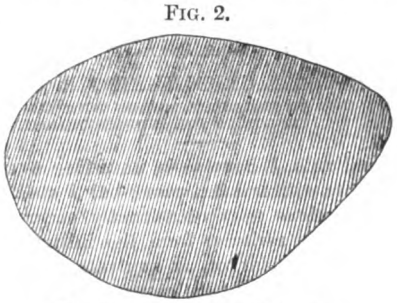
were examined and found to be healthy, except for a small patch of disintegrating caseous material at the posterior part of the right upper lobe—probably a caseous bronchial gland.

Microscopical examination showed the tumour to be a so-called "solitary tubercle," exhibiting its truly tubercular nature by perivascular lymphatic growths and giant-cells.

CASE 3.—F. A. H——, aged nineteen, admitted under my colleague, Mr. Couper, for necrosis of the jaw, toe, and tibia, in May, 1879. The notes are by Mr. Fenton Jones. He had had disease of his bones for upwards of a year. In January, 1879, headaches, to which he had always been subject, began to get worse, *his head was drawn back, and his back arched forwards, so that he rested on his shoulders and buttocks.* These symptoms—the headache, retraction of head, and arching of back—were aggravated at intervals in a paroxysmal manner, sometimes three or four times a day, the fits lasting from ten minutes to two hours. The patient had no warning of these attacks, which always occurred when he was in bed. He cried out loudly in the attacks. The only limb which was convulsed was the left hand, which he opened and shut continuously. He never passed water during a fit, and was not always quite unconscious. Always vomited freely after the fits, which relieved him, the headache disappearing, and a sound sleep following. I saw the patient on July 18th. The last fit he had had was on July 13th; it lasted longer than usual—nearly four hours. When he came under my observation he was perfectly intelligent and described well his condition. His headaches, he said, commenced at the root of the nose, radiating over the top of the head, and down the back of the neck to the situation of the seventh cervical spine. Sometimes he had pain in the temples. No motor or sensory paralysis. He could not, on account of the disease of his leg, be made to stand or walk. Sight had become defective since occurrence of fits. Objects on opposite wall of ward sometimes seemed double, sometimes as a bright spot. He could read small type—B, 0, 5—at a distance of two feet. Ophthalmoscopic examination showed double optic neuritis, each papilla being much swollen and ill-edged, the veins very large and tortuous. A few hæmorrhages were seen in vicinity of disc. Smell and taste tested and found good. Urgent vomiting now came on, which nothing relieved. He had some abdominal pain, his pulse became very rapid, and his temperature rose. He died on July 25th. The vomiting continued up to the time of his death, and his temperature when he died was 104°.

Necropsy.—A tumour of the size shown in diagram (Fig. 2) was found to occupy the left cerebellar fossa, and com-

FIG. 2.



Exact size and outline of tumour.

pressed the left lobe of cerebellum. For the following valuable report of its exact relations, and the drawings, I am indebted to my colleague, Mr. Frederick Treves:—"On examining the upper surface of the cerebellum nothing abnormal could be seen or felt. The cerebellum was removed with some difficulty, the left lobe being adherent to the dura mater, and when removed it was found that the tumour had been left behind in the cranial cavity, and was attached to the dura mater covering the occipital bone. The growth was perfectly smooth, regular in outline, and egg-shaped. No brain matter was adherent to its surface, and it gave the impression that it had been lying almost free in its cavity in the cerebellum. Examined *in situ* the growth was found to occupy the left cerebellar fossa, lying with its long axis coincident with the course of the occipital sinus; on its inner side it was bounded by the falx cerebelli, and its outer surface was about a finger's breadth from the lateral sinus, as it runs into the mastoid process; while its apex nearly touched the posterior margin of the foramen magnum. The tumour was adherent to the dura mater by a surface about the size of a fourpenny piece. On further examination it was found that the tumour had occupied the interior of the left lobe, inclining especially towards its under surface. A portion of the cortical matter, indicated in the diagram (Fig. 3) by the deep shading, was entirely absent; this portion coinciding with the spot at which the

Digitized by Google

growth had become adherent to the dura mater. The faint shading indicates the extent and position of the hole left by the removal of the tumour and the extent of attenuated cortex. On replacing the brain matter torn in removing the

The deep shading indicates the extent of complete destruction of cortex; the faint shading the extent of attenuated cortex.

left lobe it was found to be extremely thin, in some places a mere film. The 'tonsil' was quite free from encroachment. The nerves of the medulla were individually examined, but appeared quite normal. The dura mater appeared healthy; the attachment of the tumour to it was not very close." The growth was tubercular, similar to the last case.

(To be continued.)

A CASE OF GONORRHŒAL OPHTHALMIA, WITH SOME NOVEL SUGGESTIONS AS TO TREATMENT.[1]

BY GEORGE CRITCHETT, F.R.C.S.,
CONSULTING SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL
OPHTHALMIC SURGEON TO THE MIDDLESEX HOSPITAL.

As a general rule I have been unwilling to encumber medical literature with isolated cases, but I am disposed to think that exceptions may occasionally occur in which, either from extreme rarity or from the initiation of some new method of treatment, or, at any rate, a method very rarely employed and but little known, some fresh starting point may be established. Acting on this principle, and influenced by these motives, I am induced to bring the following case before the notice of the profession:—

Louisa C——, aged two and a half years, was brought to me at the Middlesex Hospital on the 15th of May, 1878. Her left eye presented all the appearances of acute gonorrhœal ophthalmia, and the collateral circumstances confirmed this diagnosis, as the child had a profuse yellow discharge from the vagina, with considerable swelling and irritation of the mucous canal. The lids were of a bright red colour and much swollen, and so densely infiltrated that even when the child was placed under the influence of an anæsthetic it was found impossible to separate them so as to ascertain the condition of the cornea. Yellow and rather thick matter was exuding from between the lids.

Judging from past experience, seeing the extreme acuteness and severity of the symptoms, the difficulty in separating the lids or exposing the cornea, and the impossibility of getting any solution into contact with the conjunctival surface, I relinquished all hope of saving the sight. I have never in the course of my experience known such a condition eventuate otherwise than in the total destruction of the eye. Under these circumstances I determined to adopt a somewhat heroic and novel proceeding, and one that has not, I believe, been published. I passed a small silver director under the upper lid as far as the edge of the orbit, against which I kept it pressed; and then, with a small, sharp-pointed bistoury, I completely divided the lid perpendicularly as far as the margin of the eyebrow. In order more completely to uncover the cornea, I separated the two angles of the divided tarsus, and fixed them with fine sutures to the skin of the eyebrow. The cornea looked steamy, but not ulcerated, and was buried in chemosed conjunctiva. The immediate effect of this proceeding was to diminish the redness and swelling of the lids and conjunctival membrane and completely to expose the surface.

In the subsequent treatment of the case I was materially assisted by the house-surgeon, Mr. Dixon, who carried out my directions with great care, skill, and assiduity. A solution of nitrate of silver—thirty grains to one ounce—was painted over the entire surface of the conjunctiva three times daily, the eye was frequently cleansed and syringed with a solution of alum—ten grains to one ounce,—and a piece of linen moistened in the solution was kept constantly applied. This plan was continued, with gradual abatement of the symptoms, for a month; a weaker solution was then substituted, and at the end of six weeks from the commencement of the treatment the eye had recovered with a perfectly bright, healthy cornea.

At the termination of another fortnight the child was again placed under the influence of an anæsthetic, when I pared the edges of the divided lids and brought them together with fine sutures. Good union occurred, the deformity is very slight, and the lid perfectly performs its function.

I may add that during the early part of the treatment the other eye was kept carefully closed with strapping so as to prevent any risk of inoculation.

To some it may seem that this rather novel proceeding was of too heroic and severe a character, but it at least had the merit of success. Every case of gonorrhœal ophthalmia, the result of direct contagion, that has come either under my care or my observation has been so uniformly attended with loss of the affected eye that I should certainly adopt a similar proceeding on any future occasion, and I beg to commend it to the attention of the profession. It seems to fulfil every indication: it relieves the immediate tension, and the strangulation with which the cornea is threatened; it permits the free escape of the matter, and enables the surgeon to make a thorough use of caustic and astringent remedies; while the slight subsequent scar on the lid is a small price to pay for a rescued eye.

[1] Read at the Ophthalmic Congress at Amsterdam in 1879.

CASE OF SEVERE LACERATED WOUND OF RIGHT FOREARM TREATED BY DRY AND INFREQUENT DRESSING.

BY EDWARD POTTS, M.R.C.S. ENG.

ON October 11th last I was asked to see a man who had just sustained a severe injury to his right forearm whilst at work. On examination I found the integument torn up from the front of the limb, from the level of the wrist to within two inches of the elbow-joint. The flap was left attached above by a broad base corresponding to the whole width of the forearm. The superficial flexor muscles, with the lower part of the radial artery, where it lies between the flexor carpi radialis and supinator longus invested by the deep fascia, were exposed, but uninjured. There was very little hæmorrhage from a few superficial veins; this was readily controlled by torsion and pressure. The flap was brought down, and its edges accurately adapted by five silver sutures loosely applied. A large square piece of perfectly dry lint was laid over the wound, and the part was enveloped in a thick padding of cotton-wool. A straight wooden splint was then applied to back of forearm, and the whole carefully bandaged; the limb slung in an easy position, with the hand resting over middle third of sternum.

The patient had rather a restless night on the one succeeding the injury, but inasmuch as he complained of little pain, and there was an entire absence of traumatic pyrexia, the dressings were not removed until Oct. 17th—six days after the receipt of the injury. Then I found the lint slightly stained with blood and healthy pus. Hand slightly

Digitized by Google

œdematous. No bagging, and very little pain on pressure. I redressed wound as at first; more thickly padded the hand with cotton-wool, and placed, in addition to the splint on back of arm, another one of gutta-percha over the dressing on flexor aspect.

On Oct. 20th I removed sutures and renewed the dressing. On making gentle but steady pressure on the flap from above downwards, about three teaspoonfuls of healthy pus escaped from margins of wound. Splints readjusted as before.

Oct. 23rd.—Dressing again renewed. Flap somewhat retracted, leaving small granulating surface at lower end of wound, otherwise doing well. Patient is anxious to know when he may go to work. Very little discharge. Union between flap and subjacent tissues seems tolerably firm.

27th.—Redressed as before. Very little discharge. Discontinued use of gutta-percha splint.

I consider that the man will be able to resume his employment in ten days or a fortnight.

Remarks.—I have had the opportunity of seeing many cases of severe mechanical injury, involving great laceration of soft parts, fractures of important bones, and injuries to nerve-centres, treated by means of "dry and infrequent dressings" by Mr. Gamgee in the wards of the Queen's Hospital, Birmingham; and I must say I was astonished at the almost unvarying success that attended this manner of treatment. I had not, however, before had the opportunity on my own responsibility of treating a case of any great severity by this method. I determined therefore—bearing in mind that the three great factors in the process of wound healing were "rest, position, and pressure"—to give the "dry and infrequent dressing" a thorough trial; and I think the result attained in this case would be sufficient to satisfy the most enthusiastic votaries of antiseptic surgery, and to justify us in regarding the "dry and infrequent method" as a step in the right direction and worthy of trial. From its simplicity, and the inexpensiveness of the materials, it is undoubtedly the dressing *par excellence* for the general practitioner. There is an entire absence in this method of any elaborate detail; we need only remember that, in order that the healing process may proceed satisfactorily, the injured part must be placed under those conditions which will insure the most perfect rest. Moisture favours the suppurative and delays the healing process: hence let our dressings be dry. We cannot renew our lint, cotton-wool, bandages, splints, or any other material generally used, without a disturbance of rest: hence let our dressings be infrequent. We must not, however, lose sight of the fact that general principles must ever guide us; that while no single method of treatment is universally applicable to all wounds, yet the "dry and infrequent method" places an injured part under the most favourable condition, and so best assists the natural reparative process.

Newcastle-on-Tyne.

A CASE OF CHRONIC DUODENITIS; ASCITES; JAUNDICE.

By BERNARD KELLY, M.D.

THE notes of the following case may be of interest as affording an instance of a somewhat rare cause of icterus, the symptoms of which, so far as they may lead to a correct diagnosis, must necessarily be obscure during life.

Margaret S——, aged forty-five, sent for me on March 28th last. The patient had been married about twenty-three years, but never bore a child, and had passed the critical period some two years previously. She had just left hospital, where she spent seven or eight weeks. The following condition presented itself. Her body was emaciated to an extreme degree and intensely jaundiced; the abdomen tense from ascitic fluid. The bowels were much relaxed, the fæces exhibiting the usual *putty-like* appearance characteristic of the disease. The pulse was 100, and never sank below this point till the final issue, a fact which proves conclusively that cholæmia does not always succeed in retarding the heart's action. The urine was scanty and deeply tinged with bile, so much so as almost to resemble porter. She complained of persistent and deep-seated pain in the right hypochondrium. There was slight œdema of the feet and ankles, notwithstanding the patient had been long and necessarily confined to the recumbent position. The appetite was all but abolished; but at no time had there been either nausea or vomiting, neither was there coloured vision, nor hyperæsthesia, although she had some time previously to my seeing her suffered much from the latter symptom, showing that in the long run the nervous system may lose much of its natural sensibility, or may adapt itself, so to speak, to the morbid conditions that surround it. Although the entire history and aspect of the case precluded even the shadow of a favourable prognosis, I deemed it my duty, nevertheless, to render the few days that remained to her of life as comfortable as possible, while giving her the benefit of any chance that might be derived from the only treatment which seemed rationally predicated. With this view the following mixture was ordered:—Bicarbonate of potash half an ounce, spirits of chloroform an ounce, tincture of opium a drachm, liquid taraxicum, concentrated, an ounce and a half, water to twelve ounces; a tablespoonful to be taken every two hours. The patient took well to the medicine, saying it warmed her (I should have mentioned that she experienced an irksome feeling of coldness), but, apart from this, the only sensible effect produced by its use was a slight alleviation of the hepatic pain; the bowels also were not quite so relaxed. The urine continued scanty, and saturated with bile. I visited the patient regularly every day till the 8th of April, when, observing no material improvement in her general condition, I omitted the potash, and substituted quinine in the proportion of twenty-four grains and iodide of potassium a drachm and a half, the other ingredients to be left unaltered. The distension of the abdomen being very great and impeding the respiration, I strenuously insisted upon the necessity of tapping, but all to no avail, as, to use her own words, "she knew she would die," and it would be only adding unnecessary torture to her last moments. The fatal issue was not long protracted, as she died on April 11th.

A partial necropsy was obtained by special favour, and was made three days subsequently. The abdomen contained about a gallon and a half of serous fluid of the same colour and consistence as the urine. The stomach and intestines, large and small, were quite healthy, empty, and distended with gas. The liver was enlarged and of a greyish slate colour; but otherwise presented nothing morbid or abnormal. The gall-bladder was enlarged and filled with fluid bile, but contained no calculi. The duodenum was greatly thickened and its tube much diminished, especially in its middle or perpendicular portion—the result of chronic inflammation—thereby completely obstructing the orifice of the ductus choledochus, and preventing the consequent passage of bile into the intestine.

Had the real state of things, as shown by post-mortem examination, been recognised before death, cholecystotomy might have been performed to some advantage, perhaps in prolonging the patient's life, by giving free exit to the long pent-up bile and relieving the passive congestion of the liver. In the present case, it could have been very easily accomplished, owing to the great turgescence of the gall-bladder, which extended considerably below the margin of the liver. The ascitic fluid could also have been evacuated in the same operation, thereby achieving a twofold object at a single stroke.

Rotherhithe.

RUPTURE OF FALLOPIAN TUBE.[1]

By C. J. RAYLEY OWEN, M.R.C.S., &c.,
LATELY RESIDENT OBSTETRIC OFFICER, ST. MARY'S HOSPITAL.

MARY D—— was taken ill on January 9th, 1880. She was thirty-nine years of age; married twenty years; had four children, no miscarriages. Youngest child is a year and three-quarters old. She had rheumatic fever when young, but heart was not affected. Catamenia began at fourteen, natural, every four weeks, lately every three weeks. She has "put on" a good deal of fat latterly, and her strength was severely taxed in the middle of December from nursing a sick child. Her last period in the beginning of December was natural, but ever since she has suffered much from pains in the back and stomach. On January 7th she thought her period had come on, but as there was only a slight discoloration of her diaper, concluded it had passed off.

[1] Paper read and specimen exhibited before the Harveian Society, Jan. 15th, 1880.

Digitized by Google

On the morning of January 8th she had been reaching about a good deal, when she suddenly felt "something give" in her right side, and almost immediately fainted away. (This was only found out after death.)

In the afternoon, when my father first saw her, she had been very sick, and only recovered from one faint to go into another. In the intervals she was quite sensible, and complained of severe pain in right iliac and hypochondriac regions, not increased by pressure. Face and hands cold and moist. No pulse in radial, carotid, or temporal arteries. Tongue clean, pale, and flabby; heart's action intensified; no bruit; chest normal, also abdomen. He conjectured some small vessel had given way, but where it was impossible to say.

Ordinary remedies for collapse were ordered, with ammonia and champagne. At midnight, when I saw her, she had rallied from her collapse; pain in right side much less, not increased by pressure. Respiration 36, very "sighing;" temperature 96·6° in mouth. After free stimulation, radial was felt to be beating at 120. This condition lasted till six A.M. on the 9th, when nutrient enemata were ordered, as sickness had returned, but she became unconscious about mid-day, and died soon after.

A post-mortem was kindly allowed, and was made twenty-six hours after death by Mr. Marsh, of St. Mary's Hospital. The body was warm; rigor mortis slight; much adipose tissue on abdomen. Lungs and heart healthy, no fat or degeneration about latter, which was small. On opening abdomen it was found to be full of thin pale blood; organs healthy, but very pale; from the right side a quart of thick black clots were removed. While about to examine the uterus it was found that both ovaries were small, cystic, and atrophied. The left Fallopian tube was small; in the right one, a quarter of an inch from the uterus, an opening of the size of a horse-bean was seen, from which a little fibrinous material was oozing; the tube was enlarged throughout its entire length to the size of a pipe-stem, but where the opening existed it was as large as a No. 10 catheter. The uterus was somewhat stained and congested near the tube, while the uterine mucous membrane was much thickened; the opening was in only the upper aspect of the tube. Careful examination failed to detect any embryo.

Remarks.—In this fortunately rare case the entire absence of peritonitis is remarkable. Could it be due to the fact that the patient was so exhausted by hæmorrhage that there was not sufficient strength to set up inflammation? The length of time that the patient lived showed that the hæmorrhage was not proceeding from a large vessel. The most plausible theory of the rupture seems to be that the patient caught cold at her period in December; that inflammation of the tube followed, possibly ending in abscess; and that the over-exertion brought about the fatal result. It is somewhat a curious fact that before commencing the autopsy Mr. Marsh said almost the last private examination he had made was on the body of a young unmarried lady, who had caught cold at her period and died from rupture of the Fallopian tube; and here also there was no peritonitis. Although he had made some thousands of examinations, he had never seen a similar case.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. MARY'S HOSPITAL.

TWO CASES OF BONY ANCHYLOSIS OF THE ELBOW-JOINT TREATED BY SUBCUTANEOUS OSTEOTOMY OF THE LOWER END OF THE HUMERUS; UNION IN A USEFUL POSITION.

(Under the care of Mr. HAYNES WALTON.)

FOR the following report we are indebted to Mr. Henry Juler, F.R.C.S., demonstrator of anatomy at the hospital, late resident registrar:—

CASE 1.—E. S——, a domestic servant-girl, aged eighteen, ignited her dress, and her left arm was severely burned thereby. The arm did not heal for a year, and all the time it was kept straight. No details of importance respecting the nature and extent of the lesions could be obtained. For four years from the period of the accident she sought relief at St. Mary's Hospital on account of the great inconvenience and uselessness of the straight and stiff limb. Cicatrices were scattered over the limb from the shoulder to the wrist; and opposite the ulna the skin was replaced by cicatricial material. The elbow-joint was destroyed, and there was complete anchylosis. The limb was quite straight.

The patient being in good health, Mr. Walton decided on performing subcutaneous osteotomy, and endeavouring to get the limb in a bent and fixed position.

On February 1st the operation was done in the following manner:—On the outside of the arm, about the centre of the humerus and two inches above what was supposed to be the position of the outer condyle, a short vertical cut was made with a small scalpel through the soft parts down to the bone. A small saw (Adams's) was introduced in such a way as to insert the blade between periosteum and the bone, and the entire thickness of the bone was sawn through with as little disturbance as possible of the adherent parts, the finishing strokes being done slowly. A gush of venous hæmorrhage, which ensued when the saw was withdrawn, was readily arrested on the application of a small compress and plaster. The limb was bent only enough to give the assurance of the bone having been divided. In that slightly flexed state a splint was applied long enough to reach from the armpit to the wrist, and so bandaged as to insure immobility. It was bent a little more a week later, and at the end of three weeks it was placed at a right angle.

On March 1st there seemed to be very decided firmness of the limb. The patient would no longer stay in the hospital. She, however, returned three weeks later to have a photograph taken, as she promised. It was clear that bony union had been accomplished. She had cast aside her splint, and was much pleased with her treatment, and said that the arm was almost as useful as the other.

CASE 2.—An epileptic and delicate girl, aged seventeen, who had fallen into the fire three times, was in the hospital three years ago with scarlet fever, when her left elbow-joint suppurated. She returned with the arm anchylosed at an angle of 160°. The wrist was in extreme pronation and fixed. There were several scars on both arms from burns, and the left had in addition marks of incisions about the position of the elbow-joint. Mr. Haynes Walton decided on operating, and the preliminary steps were executed as in the first case, and the operation differed only in the sawing being discontinued before the bone was quite cut through, and what remained uncut being broken. Venous hæmorrhage was active till pressure was applied. The limb was bent at an angle of 90° and a long splint applied.

On the seventeenth day a very severe epileptic fit occurred. The clonic arm spasm disturbed the ends of the bones, hæmorrhage ensued, profuse suppuration followed, together with slight sloughing of the edges of the tegumentary wound. All this was accompanied by severe constitutional disturbance and threatened death of the patient. Mr. Walton thought it better not to alter the angle of the arm, and he did not, but allowed it to remain as originally placed all through. The outer wound healed very slowly, but constitutional recovery was quick. At the end of five weeks it was certain that anchylosis had set in. At the end of the eighth week the splint was left off, and merely a bandage was applied. The bones were now firmly knit in true anchylosis, and a photograph having been taken the girl left the hospital. She could feed herself with this arm.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

SEVERE WOUND OF GLOBE ON CILIARY REGION; RECOVERY WITH PERFECT VISION.

(Under the care of Mr. MACNAMARA.)

THE following case is reported by Mr. J. G. Mackinlay, registrar:—

F. B——, aged twenty, a barmaid, was opening a bottle of soda-water on the night of July 15th last, when the bottle burst and the left eye was struck by a piece of the broken glass. A doctor was sent for, and attended to the case the same night and the following day. On the 17th the patient applied to the hospital, and was admitted as an in-patient under Mr. Macnamara's care.

The condition of the left eye was as follows:—A wound

Digitized by Google

through the conjunctiva and sclerotic a quarter of an inch in length, horizontal in direction, and commencing at the outer margin of the cornea just at the equator; the wound gaped, and the ciliary body and choroid were exposed and protruding into the wound; there was also a smaller wound, a line in length, extending downwards and slightly outwards from the corneal margin, just at the spot where the larger injury began. The smaller wound was not so deep as the other; the globe was somewhat injected at its outer half, and the patient stated that she had pain at times in the eye. Mr. Macnamara ordered pad and bandage to be applied.

Next day the pain was less; the pad and bandage were continued. The girl had increased pain during the night of the 19th, and Mr. Martin, the house-surgeon, gave a dose of chloral hydrate. On the following night the pain was more severe, and was not much relieved by chloral draught. At 4 AM. on the 21st Mr. Martin gave a hypodermic injection of morphia—one-third of a grain. This gave great ease. The lower wound was healing, and the larger one did not gape so much. On the 24th lachrymation had ceased from the right eye, and there was scarcely any from the left. There was a little injection of globe in the neighbourhood of the injury. The lower wound was quite healed, and the upper one was closing up well. There was no pain or photophobia. The patient was discharged.

On Oct. 22nd (fourteen weeks after the accident) the patient visited hospital. There was a small triangular patch, of a dusky yellow colour, and slightly vascular at the seat of injury, its base towards the cornea, and extending a little over its edge. The patient stated that she had no discomfort, and that the sight of the eye was as good as ever. Vision was tested, and Jaeger No. 1 was read rapidly at normal distance.

LAMBETH INFIRMARY.

CONGENITAL MALPOSITION OF HEART AND ABDOMINAL VISCERA.

(Under the care of Dr. ROBERT H. LLOYD.)

THE following case, though not very uncommon, is still of not such frequent occurrence but that its perusal may be of interest:—

T. L——, aged twenty-four, a coalheaver, was admitted into this infirmary on June 25th, 1878, suffering from secondary syphilis, and during the course of treatment the following abnormal position of the heart, and presumably of the abdominal viscera, was observed. The heart's apex was seen to beat between the seventh and eighth right ribs, about one inch and a half below, and external to the right nipple. The mitral sounds were heard most distinctly around that spot, and the aortic sounds over the sternum on a level with the third costal cartilages. An area of dulness corresponding to the outline of the liver lay in the left hypochondrium and the right hypochondrium was occupied by a resonant space presumed to be the stomach. The right testicle was lower than the left one.

The patient's previous history was to the effect that he had enjoyed good health from the age of twelve, but he had been told that up to that period he was a sickly child. He had three brothers and a sister, all older than himself, and enjoying good health.

Dr. Wodehouse of Reading, who also saw the patient, stated that he once had a similar case under his care at the dispensary at Reading.

STRATFORD-ON-AVON INFIRMARY.

EXTENSIVE WOUND OF OUTER SIDE OF THIGH BY THE HORN OF A BULL.

(Under the care of Mr. LUPTON.)

LEVI B——, aged forty-five, was admitted on Jan. 15th, 1879, with an extensive laceration of the skin and fascia on the outer side of the left thigh. It was a ⊢-shaped wound, the long arm extending from about two inches below the great trochanter some seven inches down the thigh, and laying bare the vastus externus; the short arm ran upwards at right angles to the long one across the front of the thigh for about four inches.

The wound was brought together by sutures, and carbolised lint was applied; but it did not do well, and by Jan. 24th was in a low, unhealthy, stinking state. The man was ordered six ounces of port wine daily. From this time the wound improved, and on Feb. 2nd the port wine was reduced to two ounces, and a pint and a half of porter was ordered. The wound had now all but healed. It should be noted that this was a poor half-witted man, who for some time regularly tore off his dressings, and kicked them down to the foot of the bed; not being fit for anything, he was set to look after a savage bull.

FRACTURED SPINE.

(Under the care of Mr. RICE.)

THOMAS B—— was admitted on Oct. 31st, 1878. He was helping to place a large tree on a timber carriage when it fell back, caught him along the line of the clavicles, and forcing him backwards, fairly doubled him up. His spine was fractured, apparently in two places, at about the eleventh dorsal and the second lumbar vertebræ. The line of sensation on admission corresponded to the distribution of ilio-inguinal nerve on each side; below this there was none. He had some idea when a motion was about to pass, but not the slightest control over the rectum; the urine dribbled away. After some weeks the urine was forcibly and spasmodically expelled, being projected to a great distance, and priapism occurred. This state lasted nearly a fortnight. He was subsequently able to pass urine by voluntary effort, but a puriform residuum had to be occasionally drawn off by catheter.

This case terminated fatally in November, 1879.

JERVIS STREET HOSPITAL, DUBLIN.

CASE OF INTRAVENOUS INJECTION OF MILK.

(Under the care of Dr. MELDON.)

FOR the following interesting notes we are indebted to Mr. John Cashin, L.R.C.S.I., resident-surgeon:—

Michael M——, aged forty, was admitted on Dec. 4th, 1879. About two years before symptoms of phthisis commenced, and gradually increased until May last, when his friends were in daily expectation of his death. Dr. Meldon injected three and a half ounces of milk into his veins. The operation, which was not followed by any obstruction of respiration, gave him almost immediate relief from the feeling of weakness from which he suffered. His appetite returned; he slept well, and in a few days he was able to sit up. Soon after he was sent to the convalescent hospital, where he continued to improve, and in about six weeks was able to resume his occupation of a pawnbroker's assistant. During the summer months he improved very much, and increased considerably in weight. In November last he was attacked with pneumonia, after which he had a constant cough. The other symptoms of phthisis also returned, and increased until, unable to continue his employment, he sought admission into the hospital.

On admission both lungs were extensively diseased, and there was constant diarrhœa, which had reduced the patient to an almost moribund condition. His cough was most distressing, and he was unable to take any nourishment. As all efforts to improve his condition were of no avail, Dr. Meldon, yielding to his patient's own urgent entreaty, consented to repeat the operation of injecting milk into the veins.

On the 13th of January, assisted by Drs. Cranny, Stoker, and Kelly, and in the presence of a large class of students, Dr. Meldon injected three and a half ounces of goat's milk, at a temperature of 100°, into one of the veins of the right arm. The milk, as usual, was rendered alkaline by the addition of carbonate of ammonia, and the goat was milked at the bedside of the patient. During the operation the man complained of pain and coldness in his back, but he stated he did not feel any difficulty in breathing or pain in the head. Soon after the operation the temperature rose from 99° to 104°; his breathing for a few hours was somewhat hurried, but there was no obstruction to respiration, as in many of the previous cases. The pain in the back and the coldness remained for some hours, but the patient slept well that night, and awoke next morning greatly improved in spirits and feeling much stronger. The diarrhœa was, as in all former cases, immediately checked by the operation. For some days he made steady progress towards recovery—his appetite increased, and his cough diminished.

Dr. MELDON, in his remarks to the students, said that the operation of intravenous injectment of milk had been

Digitized by Google

received in Europe with very little encouragement, and even in New York, where there was every promise of the operation receiving a fair trial, it seemed to have fallen into disrepute. The present was the tenth case in which Dr. Meldon had performed the operation, and with a result that made him most hopeful of its success when performed in suitable cases and with proper precautions. As yet he had only resorted to it in cases where the patient's hours were already numbered. In all these cases life had been considerably prolonged, and in four the patients had been completely cured by the operation. The operation was quite free from danger if one or two points were attended to, besides those which had to be looked to in every case of transfusion. The two points which were peculiar to the transfusion of milk were, that care should be taken that the milk was alkaline, and that only a small quantity at a time, four and a half ounces being the largest amount that should be injected. Lately a good deal has been written against the operation. The opponents of the procedure might be classed under three heads. First, those who say it is *theoretically* wrong. Second, those who argue from experiments on lower animals, and, thirdly, those who believe the globules of the milk are two large to pass through capillaries. The first and last of these may be met by pointing to the fact that several cases have been successful, and in no case where the operation has been performed with proper care with regard to the two special points which Dr. Meldon mentioned have injurious results followed.

With regard to the comparative experiments on dogs, the great error had been that healthy dogs had been selected, and, comparatively speaking, an enormous quantity of milk had been injected.

Dr. Meldon stated that he had no doubt if a healthy country patient was selected for the operation, and say forty ounces of milk injected into his veins, the result would be almost necessarily fatal. This really had been the kind of experiment on dogs, and it was not surprising that the conclusions drawn from these experiments should be so unfavourable.

The cases which Dr. Meldon had cured were all cases of pernicious anæmia, and he stated he could easily understand how in that disease a small quantity of corpuscule-supplying fluid might alter the condition of the blood, and thereby effect a cure.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Estimation of Uric Acid by its reducing Action upon the Ammoniated Cupric Test.—The "Nietze-Leitner" Endoscope.

THE ordinary meeting of this Society was held on March 23rd, J. E. Erichsen, F.R.S., Esq., President, in the chair. A paper by Dr. Pavy, dealing with the quantitative determination of uric acid in the urine, was read, and the process demonstrated by the author. After this Sir H. Thompson described and demonstrated the application of the "Nietze-Leitner" Endoscope.

The following is an abstract of the paper on the Estimation of Uric Acid by its reducing Action upon the Ammoniated Cupric Test, by Dr. F. W. PAVY, F.R.S. The author first refers to the importance of being able to determine readily and with precision the amount of uric acid voided for the purpose of studying the conditions which tell favourably and unfavourably upon the uric-acid diathesis, and as a guide to treatment during the management of a case in which the uric-acid deposit occurs. The old methods of estimating uric acid could not be spoken of as meeting the requirements of the medical practitioner either as regards facility of application or precision. The method which the author desired to bring before the notice of the Society is founded upon the reducing action which uric acid, like sugar, exerts upon the oxide of copper. The ordinary form of copper test is most susceptible of application to the purpose, but the ammoniated cupric liquid, which the author has recently introduced[1] for the quantitative determination of sugar is perfectly available. With this test the reduced oxide, instead of falling as a precipitate, is held in solution by ammonia, and a simple decoloration of the liquid occurs as the reduction proceeds. The mode of preparation and employment of the test having been described, it is stated that the results obtained from observations conducted with known quantities of pure uric acid so closely harmonised with the expression that three atoms of oxide of copper are reduced by one atom of uric acid, as to justify this formula being adopted as the basis of calculation for the process. For the determination of the uric acid in a specimen of urine the reducing power is taken before and after treatment with acetate of lead. The first or total reducing action is in part due to uric acid and in part to the small amount of sugar which urine naturally contains. The addition of acetate of lead effects a precipitation of the uric acid, and the reducing power now obtained represents the reducing power of the urine, minus that of the uric acid it contained. By the difference between the two determinations the amount of uric acid is ascertained. The mode of calculation is given. Results are furnished showing the precision with which known quantities of uric acid added to urine are revealed by the process. To be certain that what is taken as expressing uric acid is in reality due solely to the presence of uric acid, the process was checked against the actual collection and subsequent determination of the uric acid. Results are first given to show that the collection and subsequent determination of uric acid can be carried out in a manner to afford reliable information, and then the two processes, the determination from the difference in the reducing power before and after precipitation with acetate of lead, and by actual separation of the uric acid, and its subsequent estimation, were applied to various specimens of urine, and the result compared. The figures obtained present a close accord, and justify confidence being placed in the results derived from the process brought forward. The author thus concludes his communication:—"This completes what I have to say about the process I have described for the estimation of uric acid. The next matter to deal with is the results obtained by its application to the urine under various conditions of health and disease. This is a matter of some magnitude which I must reserve for the subject of a future communication, but I may here state that according to the observations I have conducted, the figures that have been hitherto given as representing the amount of uric acid present will have to undergo considerable alteration." Dr. Pavy then exhibited the process above described to the Society, and further added some interesting remarks upon the estimation of the acidity of the urine by means of phenol-phthaline, a test which he also exhibited. He said that he had made comparative observations upon the amount of uric acid and the acidity, but his conclusions were not numerous enough for generalisation.

Sir HENRY THOMPSON exhibited a specimen of the "Nietze-Leitner" Endoscope. He commenced by observing that before giving a practical illustration of the new endoscope he would say a few words as to its origin and history. Endoscopy was a product of the present century. Bozzini of Frankfurt made the first attempt in 1805, and created a considerable interest in the subject. The next step was made by Tégalas of Strasburg in 1826; he applied it chiefly to the urethra and bladder. Some twenty years afterwards Cazenave in Paris, and Avery in London, experimented independently of each other. Avery constructed an instrument for examining the larynx, which has been but little modified even to the present day. He (Sir H. Thompson) had witnessed Avery's examination of the urethra in 1851. Meantime, Désormeaux of Paris carried urethroscopy further by the use of a lamp and an arrangement of mirrors for reflecting its light. For this he received a portion of the Argenteuil Prize in 1853; and obtaining subsequently the Clinique at Hôpital Necker, brought out a considerable work on "Endoscopy" in 1865. Cruise of Dublin used this apparatus, but adapted to it a stronger light. But some ten or twelve years ago Dr. Brucke of Breslau conceived the idea of carrying a platinum wire, maintained at a white heat by the galvanic current and cooled by a current of cold water, into the rectum, believing that he might then probably illuminate the interior of the abdomen, or at all events throw light enough into the bladder to enable him to see its contents through a

[1] Proceedings of the Royal Society, vol. xxviii., p. 260, and vol. xxix., p. 272.

Digitized by Google

tube introduced there. He was, however, doomed to disappointment, the light being insufficient to penetrate the tissues. About three years ago a modification of this principle suggested itself to the mind of Dr. Nietze of Vienna, who was fortunate enough to find in Mr. Leitner, the very ingenious instrument maker of that city, a co-operator who spared neither time nor expense to realise the idea. This he has done by producing exceedingly delicate apparatus adapted to enter each of the different cavities of the body, containing the galvanic light described and the water-circulating apparatus, so that the wire heated to whiteness can be carried with perfect safety into the urethra and bladder, the rectum, the back of the pharynx and nasal cavities, and even into the stomach itself. Sir Henry Thompson then demonstrated the applicability of this apparatus to the exploration of the urethra and bladder on the living body of a patient, who was there for the purpose. Finally he stated that it was not to be supposed that the endoscope should be in any case lightly resorted to. The employment of such instruments, as he had shown, necessarily involved a certain amount of irritation in the organs, and nothing could be gained by such observations except from rare and particularly obscure cases. Thus, he could not conceive a case of lithotrity in which it could be useful: the "last fragment" of which so much had been often said and which was formerly a bugbear, if not an opprobrium to lithotrity, was perfectly amenable to the treatment of modern instruments, and if a surgeon felt himself unable to deal with it, he should not attempt lithotrity at all. The Nietze-Leitner endoscope was no more wanted for stricture, retention, or stone than were the previous endoscopes; if the surgeon had skilful hands, the endoscope was useless in these conditions; if he had not skilful hands, no endoscope could make him a competent surgeon. But the new instrument, with its vastly greater power of light, might do what other endoscopes would fail to do—namely, determine the nature of a foreign body such as we find occasionally introduced from without into the bladder, cases no doubt of extreme rarity; and it might also help us to identify the existence of a villous growth in the bladder, which was not to be accomplished by any known mechanical means. Great difficulties, however, surrounded an examination in such circumstances, for it is essential, in order to see at all clearly with an endoscope, that the bladder should be partially distended with clear urine, clear water, or air, the last-named being somewhat preferable. But it must be confessed that, in conditions of diseased bladder, the urine was generally cloudy from the presence of muco-pus and blood, and that the very employment of the instrument tended still further to produce thickness in the urine. Hence it is necessary in these cases to wash out the cavity completely, leave about four ounces of pure water within, and at once introduce the endoscope tube with the utmost care. Practically speaking, the difficulty of attaining the desired conditions was sometimes considerable. Sir Henry had had the opportunity through the kindness of Professor Dittel of Vienna, assisted by Dr. Nietze and Mr. Leitner themselves, of examining several cases at the Vienna Hospital last autumn, and had had the opportunity of testing his own instrument now present here in London. He was extremely indebted to Mr. Weiss, who was present, for his intelligent and careful management of the apparatus, since it was essential for this, as well as its maintenance in good working order, that it should be under the care of a person well versed in the use of galvanic apparatus and competent to adjust, or repair, if necessary, the very delicate details which formed essential parts of this somewhat complicated but very complete instrument.

MEDICAL SOCIETY OF LONDON.

Renal and Hepatic Colic—Impaction of Gall-stone in Ileum.—Genu Valgum treated by Tenotomy and Mechanical Appliances.—Cerebro-spinal Syphilis.

AT the meeting on March 22nd, Mr. F. J. Gant, President, in the chair,

DR. DE HAVILLAND HALL communicated for Dr. F. A. Hill notes of a case of Renal and Hepatic Colic. The patient, a stout woman aged fifty-eight, while riding in a cab was seized with severe bilious vomiting and became collapsed. No jaundice appeared. The fourth day (Jan. 20th) after the attack she had three rigors and two severe attacks of spasmodic pain in the cardiac region. On Jan. 27th she had a violent attack of pain in the left lumbar and inguinal region with rigors; and a similar attack on Feb. 2nd. On April 16th she had extreme pain all over the abdomen with constant vomiting, which became stercoraceous, and death ensued. A concretion the size of a hen's egg blocked the ileum two feet from its termination; a fistulous communication existed between the collapsed gall-bladder and the duodenum. Both kidneys were studded with small cysts, and in the pelvis of the left organ a calculus was lodged.

Mr. SAMUEL BENTON exhibited a severe case of Genu Valgum cured by instrumental means and tenotomy. The patient was a boy twelve years of age, who came under notice in July, 1879. When the bones were put close together the malleoli were eight and a quarter inches apart; the left leg being more bowed than the other. In August the biceps tendon of each leg was divided subcutaneously and an instrument suggested by Mr. Baker was applied. At the end of two months there was an interval of only two inches between the malleoli, the left leg not being quite straight, owing to the extension of the external lateral ligament of the knee-joint. In January the author divided this ligament, and the instrument was again applied for a month. The legs are now perfectly straight. Although the author was not opposed to Ogston's operation, he believed that in many cases a better result can be obtained by more simple means. Cutting into a joint and filling it with bone dust was an operation attended with more risk than simple subcutaneous tenotomy. He urged great care in the selection and supervision of the instrument applied.—The PRESIDENT said operations for this deformity were now common, and numerous successful results had been published; but he feared there were others unheard-of where death had occurred, or where recovery had been protracted. The procedure just recorded was certainly safer than that of removal of the internal condyles.—Sir JOSEPH FAYRER complimented Mr. Benton on his success, and expressed his opinion as to the value of this simple operation.—Mr. PEARCE GOULD said that having lately brought before the Society a successful case of excision of the inner condyles for this complaint, he wished to state that in a similar case now under his care suppuration had taken place, with slow recovery, leaving anchylosis of the joint. He intended to break down the adhesions, and expected a fair result. He exhibited another case, where there was a distance of sixteen inches between the malleoli. There might be some danger in dividing the nerve along with the muscle in this operation.—Mr. BAKER testified to the nature and extent of the deformity in Mr. Benton's case, and considered that in testing the straightness of the leg care should be taken to keep the patella uppermost. He had never seen the nerve divided.

Dr. DRYSDALE then read a paper on Cerebro-Spinal Syphilis. After a brief survey of the history of the subject he proceeded to point out the various forms into which cerebro-spinal syphilis was divided. In some pain was the principal feature; in others the symptoms were those of cerebral congestion; in others loss of intellect was the prominent fact; in some epilepsy predominates; in others paralysis. Syphilitic headache is deep and internal in character. The congestive form is accompanied by vertigo, low spirits, dim sight, buzzing in the ears, and lowered intelligence. More than three-fourths of all cases of epilepsy supervening for the first time in adults were attributable to syphilis; paralysis often follows; the convulsion may be partial. Aphasia conjoined with right hemiplegia, or without paralysis, may occur. Dementia, melancholia, and mania, and an affection closely resembling general paralysis of the insane might be produced by syphilis. The cranial nerves most affected are the third, the facial, and the hypoglossal, then the optic and auditory; the first and fifth rarely, and, least of all, the vagus and spinal accessory. Ptosis, mydriasis, and strabismus, with headache, were indications of cerebral syphilis; complete amaurosis was not rare. Labio-glosso-laryngeal paralysis, ataxia, and paraplegia were occasionally due to syphilis.—Dr. DE H. HALL asked whether the author had included embolism in the cases of right hemiplegia with aphasia. He mentioned a case of a young woman attacked with epilepsy preceded by paralysis of the right third nerves and of the left facial. Although no direct history could be obtained, he considered

Digitized by Google

these conditions justified the diagnosis of syphilis.—Dr. C. T. WILLIAMS thought the author had tended to make the area of syphilis too large. He referred to a case of paraplegia, with lung symptoms, where a history of syphilis twelve years previously directed the diagnosis, borne out by the satisfactory result of treatment.—Dr. DEWAR mentioned a case of epilepsy with frequent spasms of the arms and legs, in which bromide of potassium had failed, but where a week's course of mercury was followed by cure.—Dr. GILBART SMITH deprecated attributing to syphilis all cases that showed rapid improvement under iodide of potassium. He mentioned a case (undoubtedly syphilitic) of incomplete hemiplegia, with aphasia and retinal changes, which quickly disappeared under the iodide. On being made an out-patient, the symptoms returned, with the addition of epileptiform attacks, but was again successfully treated by the same drug.—Dr. DRYSDALE, in reply, said that the cases of aphasia due to syphilis were those in which no cardiac affection was present, but evidences of syphilis were. The statistics of epilepsy he had given were those of Fournier, and he himself believed that epilepsy arising in adult life was probably due to syphilis. He wished to lay stress on the importance of specific treatment in doubtful cases.

THE DENTISTS ACT OF 1878.

WE understand that the subjoined memorial has been presented to the Executive Committee of the General Medical Council by the Association of Surgeons practising Dental Surgery:—

To the President and Council of the General Medical Council.

The Association of Surgeons practising Dental Surgery beg respectfully to ask your consideration of the Dentists Act of 1878, with a view to its amendment or repeal. We do so more especially at this time, as there are Medical Amendment Acts before Parliament.

We beg to point out that, as indicated in the preamble of the Act, it was intended to make provision for the registration of persons "specially qualified" to practise as dentists. That this result has not been obtained may be inferred from the fact that more than five thousand persons have been registered as dentists, whilst the highest estimate formed by those who were interested in the passing of the Dentists Act was, that not more than two thousand persons could be registered in Great Britain and Ireland to practise Dentistry. There can therefore be no doubt that a very large proportion of the persons registered do not possess the qualifications indicated in the preamble of the Act, and therefore that the registration is deceptive.

This result is due to the wording of Clause 6 of the Dentists Act, in which it is stated that "any person who (*c*) is at the passing of this Act *bonâ fide* engaged in the practice of dentistry or dental surgery . . . . shall be entitled to be registered under this Act." No interpretation of the terms "Dentistry or Dental Surgery" having been given, each person claiming registration has interpreted these words after his own fashion, and consequently many persons have been placed on the Dentists' Register without any claim to be "specially qualified."

It is quite true that the General Medical Council by Clause 13 can "cause to be erased from the Dentists' Register any entry which has been incorrectly or fraudulently made;" but until the words alluded to in the preceding section are clearly interpreted, it will be impossible for the General Medical Council to remove the names of persons who may be felt not to be "specially qualified" as Dentists.

Even if the General Medical Council could act under this clause, the delay and difficulties in carrying into operation the action of the clause are so great, that much harm will be done before the desired result can be obtained. For example, the Council of the Royal College of Surgeons in Ireland have represented to the General Medical Council that the name of a certain individual has been removed from the register of dental licentiates of that College on account of his "admitted unprofessional conduct," yet such are the arrangements by which this case can be brought before the General Medical Council and finally settled, that it may occupy more than a year from the present date, the name of such person remaining all this time on the Dentists' Register.

From this it may be seen that a large and important body like the General Medical Council, meeting at rare intervals, and having special and important business of its own to attend to, is not that best qualified to undertake the duties assigned to it by the Dentists Act.

That such was felt to be the case is made manifest by a reference to the Lord President's original Bill (1878), in which by Clause 23 the power was given to the General Medical Council to frame "a scheme for the examination, licensing, and registration of dentists," and such scheme, when approved by the Privy Council, shall have effect as part of this Act, subject to being from time to time revoked, altered, and added to by a subsequent scheme submitted by the General Medical Council to and approved by the Privy Council.

Under this clause it would have been possible for the General Medical Council to have established a board, the regulations of which, under the control of the Privy Council, would have had all the force of the clauses of an Act of Parliament, yet which could be modified according to circumstances.

This was evidently the object the General Medical Council had in view when it passed a resolution on the 4th of July, 1878, to the effect, "that the Council desires to express its wish that the Bill entitled the Dental Practitioners Bill be brought into conformity with the dental clauses of the Lord President's Bill." This recommendation of the General Medical Council has been disregarded, and instead of the Council being authorised to frame a scheme as above shown, the whole work of carrying the Act into operation has been thrown upon the Council itself, which has thereby been made an executive and not a legislative body.

Lastly, the Dentists Act enables certain Doctors of Dentistry to be registered, who can thus use the title of Doctor, a proceeding which will render it *impossible* to carry into effective operation the 24th Clause relating to unregistered persons in the Medical Act, 1858, Amendment Bill, 1879, of the Lord President, whereas also the Act does not prohibit persons from assuming the title of surgeon in conjunction with that of dentist by those who do not possess any surgical qualification whatever.

We, therefore, earnestly pray that the General Medical Council will be moved to take such measures with reference to the Medical Amendment Act now before Parliament as will secure a due interpretation of the terms "engaged in the practice of Dentistry or Dental Surgery" made use of in the Dentists Act, Clause 6.

That they will also be pleased to cause to be introduced in Clause 24, line 37, in the Lord President's Bill, after "takes, or uses," the words, either alone or conjunctively with any other word or words, "the designation," &c.

Finally, to consider whether it will be for the convenience of the Medical Council, and for the interests of dentists, that Clause 23 of the original Bill of the Lord President should not be made law, and the Dentists Act either repealed or modified accordingly.

Believing that such modifications are absolutely necessary, we earnestly and respectfully request the serious attention of your Council.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. G. Scorer of Piccadilly bequeathed £500 to the City of London Truss Society, £250 to the Cancer Hospital, £250 to the City of London Hospital for Diseases of the Chest, £200 each to St. George's Hospital, the Brompton Hospital for Consumption, the London Hospital, the Westminster Hospital, and the Charing-cross Hospital, £100 to the Royal National Hospital for Consumption at Ventnor, £100 to St. Mary's Hospital, and £50 to the Hospital for Sick Children; and 1000 guineas each to St. George's Hospital, the Brompton Hospital for Consumption, the London Hospital, the Westminster Hospital, and the Charing-cross Hospital, upon trust to invest the same in Three per Cent. Consols, and apply the annual dividends between fifteen patients of each hospital on leaving. Mr. William Fisher of Sheffield bequeathed £250 each to the Sheffield General Infirmary and the Jessop Hospital for Women, payable within six calendar months after the death of his wife. The Goldsmiths' Company have given another £100 to the Royal National Hospital for Consumption, &c., at Ventnor. The Arbroath Infirmary has become entitled to £500 under the will of the Rev. David R. Louson, minister of the Scotch Church, Carlisle.

THE LANCET.

LONDON: SATURDAY, APRIL 3, 1880.

BY "qualified quacks" we mean persons duly qualified by the possession of a licence or diploma—in some instances of more than one of these legal instruments—to practise medicine, who, nevertheless, so conduct their business as to place themselves, practically, outside the pale of a profession governed by the unwritten, but perfectly well understood, laws of etiquette; and whom it is impossible to distinguish, by the simple fact that their names are to be found in the Medical Register, from the great camp-following of "quacks." It will, doubtless, at first sight appear that the possession of a legal qualification effectually relieves the practitioner from the imputation of quackery, and that being so "qualified" he must enjoy a citizen's liberty to order his life as it shall please him, or as may seem to his personal judgment most promising of success. Would a duly ordained minister of religion—we use the broad term purposely to include the recognised teachers and preachers of every church and sect—be considered free to exercise his calling wholly without regard to the rules of the ecclesiastical body from which he derived his "orders"? Surely the title is morally, if not *legally*, effaced by any act which practically severs connexion with the fount of honour! A peer who could not be summoned to the House of Lords or be received at Court because of some personal or social disability, would be virtually degraded from the ranks of nobility, although his title had not been suppressed by any formal act of the Sovereign, based on the ground of attainder, and he might, therefore, be restored to honour on amendment. The case stands thus with the holders of legal licences to practise medicine who do not conform to the laws and usages of the profession. They may be qualified, but they are not the less on that account quacks or pretenders in so far as they claim to be members of the profession to which the legal documents they undoubtedly possess would, in the absence of personal disability, give them a title to belong.

The doctrine that a man may be qualified in medicine, and yet not practically recognisable as a member of that profession, may, as we have said, strike the reader as a novelty, but it is, in truth, a recognised principle of all other professions except our own, and in regard to no other calling in life is it so necessary for the public welfare that the dogma should be promulgated and made to be generally understood. The barrister may be disbarred, the clergyman unfrocked, the holder of Her Majesty's commission in the Army or Navy cashiered, and after the withdrawal of titular powers there is an end of the delegated authority. Unhappily the senates, colleges, and corporations armed with the power to grant licences in medicine and surgery have of late years fallen into a practice of selling their diplomas very much as TEKEL dispensed his indulgences; and there is great need that a LUTHER should rise up and denounce a traffic which conflicts with the interests of public health, and is therefore antagonistic to the interests of the medical profession. The abnegation of control which the licensing bodies have so long practised with respect to their jurisdiction over their own graduates, fellows, members, and licentiates, cannot, however, absolve the profession itself from the responsible duty of watching over the public welfare. The general responsibility is, indeed, increased by the negligence of those upon whom it officially devolves to keep the great body of medical practitioners free from any stain of quackery! Never was there a time at which it was more important that the profession should discharge this incumbent duty than the present moment. It must, we fear, be accepted as a postulate in the argument that the bodies empowered by law to grant qualifications to practise refuse to exercise the cognate and implied function of controlling the practice of their licentiates. Neither the Colleges of Physicians—, corporations specially created to maintain the dignity and order the practice of the medical profession—the Colleges of Surgeons—called into existence with similar aims,—nor any one of the universities, will discharge their obvious duty in this matter. All these bodies are engaged in the competitive sale of licences, and it seems to be a subject of indifference to them what the holders of their diplomas do when once that bargain is concluded. Perhaps there is something essentially incompatible in the two functions of licensing and controlling. If that be true, the sooner an Academy of Medicine, or some body which shall be exclusively *censorial* in its function, is created, the better.

Scarcely a day passes in which we do not receive earnest appeals and remonstrances from acknowledged members of the profession against the misconduct of qualified quacks who advertise in the lay papers, send out circulars, and resort to the most flagrantly disreputable methods of touting for public patronage. It would be an extreme measure to hold the perpetrators of these offences against etiquette, and we take leave to say decency, up to the contempt they deserve, and we are, for the present, compelled to treat the just complaints of our correspondents with a reserve which is altogether opposed to our own feelings, and must, we fear, in a large number of instances, appear ungracious, or possibly, even, in some instances, may be misconstrued to imply a certain kind of acquiescence in the practices they denounce Certain it is that, from some cause, the evil against which the profession needs to make a new and determined stand is on the increase. It is difficult to take up a daily or weekly paper without finding advertisements aimed more or less directly to bring practising members of the profession under public notice as claimants to special favour. This is an evil which derives the strength by which it flourishes from the doubtful, though not easily denounceable, proceedings of men who are themselves respectable, but indirectly encourage the artifices of others who are not. It is vain to iterate the once received axiom that "no respectable member of the medical profession advertises," when the columns of the daily newspapers abound with advertisements of works bearing sensational titles, and addressed to the public by medical men, of instruments, preparations, and appliances, advertising, if not *intended* to advertise, the names, qualifications, and addresses of men who are not only engaged in, but who court, practice! Those who do such things should think how much beyond their own personal burden of responsibility is incurred by the course they take.

Digitized by Google

Under the shadow of this practice of indirect advertising, carried on by men who are respectable and even eminent members of the profession, has sprung up the practice of open advertising by qualified quacks. If there were no respectable transgressors in this respect, it would be easy to denounce the whole body of "advertising doctors" as unworthy of public confidence; but, as the case now stands, whenever this wholesale denunciation is made, there is the consciousness that the next post may bring cuttings from newspapers showing how fully-qualified and really good men are among the delinquents.

We will not pursue the subject further into detail, although if there be not some marked change for the better in the practice of seeking publicity by sinister or at best equivocal means, such as advertising, and the distribution of circulars, we shall be compelled to consider whether it is not a duty which cannot be longer evaded to proceed to extremities and name those who make so light of professional honour as to drag it in the dirt before the eyes of the public. Meanwhile we appeal to the profession as a whole to make it clear to its members that conduct such as that to which we have alluded is not of a nature to be condoned or tolerated. If it be true, as the history of our profession certainly seems to show, that no practitioner, however temporarily sought-after, can be permanently successful unless he secures the respect and confidence of his compeers—in a word, of the only men competent to appraise his real merits—it should be in the power of the profession to control the conduct of its members in this particular. We are convinced it *is* well within the power of the profession to do so; and simply because the authority vested in the body of practitioners is not exercised this evil grows apace. The self-respect of the great majority must discountenance the practice of the few—we fear it may be said the *many*—who in the haste to be rich, or chagrined with a disappointment which is the recompense of their own impatience, are discrediting a vocation wherein only those who are strictly honourable deserve to succeed.

THE "sanitary organisation of nations" (we borrow the phrase from Dr. BOWDITCH, of Boston, Mass.) is about to become, it would appear, a mission of the United States of America. The initial step in carrying out this mission we take to be the joint resolution we had occasion to notice a short time ago, and which was introduced into the Senate and also into the House of Representatives in February, authorising the President to take the initiative in calling together an International Sanitary Conference at Washington. To this Conference it is proposed that the several Powers having jurisdiction of ports likely to be infected with yellow fever shall be invited to send delegates for the purpose of securing an international system of notification as to the actual sanitary condition of ports and places under the jurisdiction of such Powers, and of vessels sailing therefrom.

Hitherto the United States have, as a rule, abstained from taking, or have not had, part in the various International Sanitary Conferences held in Europe; and it is a curious feature in the sanitary activity developed in the States since the formation of the National Board of Health that one of the earliest outcomes should be the manifestation of a desire to cultivate sanitary administrative relations with other nations. To a race so pre-eminently practical as our Transatlantic brethren we should have imagined that the almost painful futility of the several International Sanitary Conferences which have been held in Europe in bringing about administrative accord in hygienic measures between the several Powers represented in them would have exercised a deterrent effect—if, indeed, it had not induced contempt for this apparently hopeless method of endeavouring to secure international sanitary concord by means of conferences. On the contrary, the United States propose to act as if they saw in our failures in this direction an additional argument for their intervention. Let us hope that their action in the matter rests on an accurate knowledge of the difficulties which have to be overcome in promoting an international sanitary organisation, and is not the mere product of a theoretical conception of the advantages that would arise if nations would combine against certain sanitary evils which concern them in common—a conception, it may be surmised, very apt early to occur, and to influence the first-formed Central Sanitary Organisation in the States.

But what prospect has the United States of prospering in her self-imposed mission, even when restricted at the outset to the single question, which so intimately concerns her, of yellow fever? Few things have excited so much surprise in this country in connexion with the administration of the United States Board of Health as the prominence which it has given, and is still giving, to measures of quarantine in its suggestions for the limitation of recent prevalences of yellow fever. It is true that a broader signification is given to the term than is commonly attached to it by European nations, in the sense that a system of medical inspection of ships and passengers is grafted on the quarantine regulations. Generally greater prominence is given to sanitary matters in regard to them, and the health officer is required to exercise some discretionary power. But the quarantine element is veneered rather than essentially modified by these changes. For example, in ships from foreign ports, it is sufficient that they should have sailed from a port, or touched at any port, or communicated with any ship on her voyage, in which either yellow fever, or cholera, or plague, or small-pox as an epidemic, or typhus fever also as an epidemic, has prevailed, in order to render them liable to quarantine. Here, true to the old quarantine fancies, the *possibilities* of infection, however remote and inconsistent with our actual knowledge of the mode of dissemination of communicable diseases, are made to govern the practice. The same is true of the regulations laid down in inland quarantine, and in a Bill now before the House of Representatives it is proposed that when a place shall have been officially recognised by the President to be dangerously infected with contagious or infectious disease, it shall be unlawful to transport goods or persons from such a place into a State other than that in which such a place is,—in other words, an endeavour is to be made to cut off all communication between the infected place and State and other States.

Unless human nature differs singularly across the Atlantic from what it does here, we may expect that these regulations will prove in practice of no higher value than other "paper

Digitized by Google

plausibilities" of quarantine. If they have been devised with a view of conciliating the opposed schools, so to speak, of quarantinists and hygienists, we imagine that they will fail, for each will scarcely be prepared to assent to so much of its notions being overlapped by the notions of the other. In fact, we cannot but regard the views as to quarantine entertained by the National Board of Health as a retrogression, not an advance, in hygienic practice. The world is not so barren of experience as to quarantine that the system should be accepted as a sort of public-health necessity. In England we have been steadily endeavouring now for some years to bring our sanitary administration as to infectious diseases, whether ordinary or foreign, into such form that every locality shall be at all times in a state of preparedness to deal with them with the least amount of disturbance to the current affairs of life and the least need for the exercise of any special powers. We are not prepared to say that some greater powers of restraint in respect of foreign diseases than is possessed under the Public Health Act might not be desirable, but such restraint, if experience here goes for anything, should certainly not be of the nature of quarantine. We had hoped that English experience in this matter would have exercised much influence on medical opinion in the United States, and that the new National Board of Health, having nothing to unlearn, would have been able to approach the subject untrammeled by those traditional elements which go to make up the system of quarantine.

WHATEVER the party triumph to be achieved in the current elections, it is to be hoped that the Parliament that is to be will be more earnest in vital and sanitary questions than that which has just expired. The tendency of the late Parliament to put every duty of an urgent character into a permissive form nullified half of its Acts. One conspicuous example in point is to be found in a clause of the Poor-law Act of 1879, which was meant to provide better accommodation in the metropolis for infectious disease. The clause purports to give power to the Metropolitan Asylums Board to contract with the local authorities for the reception in hospital of persons suffering from dangerous infectious disorders; and further gives power to the local authority to recover any expenses for maintenance from such persons. This clause should have been followed by another requiring the local authorities to enter into such arrangements, and, failing to do so within a given time, giving power to the Local Government Board to do so for them. But such was not the manner of legislation in the late Parliament. Its domestic policy was not "spirited." It put into the clause we are criticising the word "may" instead of "must," and it entirely omitted to put any pressure on the local authority; so that it is a matter of will or disposition with them, and not of requirement. The consequence is, that men like Mr. GALSWORTHY and Sir EDMUND H. CURRIE, who spend a great amount of their valuable time at the fortnightly meetings of the Metropolitan Asylums Board, have to waste it in passing such resolutions as the following:—

"That a circular letter be now addressed to the various metropolitan vestries and district boards inquiring *whether they are desirous* of availing themselves of the provisions of Clause 15 of the Poor-law Act of 1879 by contracting with the managers, and, if so, to state the approximate number of beds which they would wish to be provided for them in the managers' establishments, if suitable arrangements can be made."

This resolution clearly shows that the whole thing is left to the option of the local authorities, who will act irregularly and without system. It is highly unjust to the members of the Metropolitan Asylums Board—most of them busy men—to make such weak laws, which can bring nothing but discredit and disaster on themselves and the local authorities.

A perusal of the minutes of the recent meetings of the managers of the Metropolitan Asylums District shows that they are embarrassed with the claims of rival epidemics, and have to shut out of one hospital cases for the treatment of which it was built, in order to make room for cases of another infectious disease for which it is not adapted, and that even then the accommodation is inadequate. Thus in last autumn it became necessary to close Homerton and Stockwell against small-pox cases, and to use them for the treatment of enteric fever cases. At Stockwell, in January, the demand for accommodation for scarlet fever cases was such that forty patients were admitted in excess of the certified capacity of that hospital, and as the cases still pressed, the accommodation for typhus had to be sacrificed to meet it. The great inconvenience resulting from these arrangements, and from the necessity of removing small-pox cases to either Deptford or Fulham, has given rise to much complaint. No doubt the managers have done the best they could; but they are hopelessly embarrassed by weak and inefficient laws. It would immensely facilitate their work if local authorities were required to make local provisions for the early ascertainment of infectious diseases and for the prompt isolation of sufferers from them, as in the recent outbreak of small-pox in St. Pancras. Until some laws to this effect of a stringent character are passed, we do not envy the position of the members of the Metropolitan Asylums Board, who are liable at any time to be overwhelmed with one or more epidemic diseases.

Annotations.

"Ne quid nimis."

AN INTERNATIONAL MEDICAL CONGRESS.

A MEETING of the delegates appointed by the Universities, Colleges, and public bodies in reference to the subject of an International Medical Congress was held at the Royal College of Physicians on Tuesday, March 30th, at four o'clock, when the following delegates were present: H. W. Acland, M.D., Regius Professor of Physic from Oxford; G. E. Paget, M.D., Regius Professor of Physic, Cambridge; R. Smith, M.D., University of Aberdeen; T.R. Fraser, M.D., University of Edinburgh; Alfred Hudson, M.D., University of Dublin; J. R. Bennett, M.D., President of the Royal College of Physicians, London; D. R. Haldane, M.D., President of the Royal College of Physicians, Edinburgh; Arthur Hudson, M.D., King and Queen's College of Physicians, Ireland; Luther Holden, Esq., President of the Royal College of Surgeons, England; F. B. Imlach, Esq., President of the Royal College of Surgeons, Edinburgh; A. Buchanan, M.D., President of the Faculty of Physicians and Surgeons, Glasgow; Professor Huxley, President of the Royal Society; E. H. Greenhow, M.D., President of the Clinical Society;

Digitized by Google

W. S. Playfair, M.D., President of the Obstetrical Society; Sir Joseph Fayrer, M.D., President of the Epidemiological Society, and representing the Medical Department of the Indian Service; Alfred Carpenter, M.D., President of Council of the British Medical Association; T. G. Balfour, M.D., representing the Medical Department of the Army.

The meeting had been convened to consider the following questions:—

1. At what period in 1881 shall the Congress be held, bearing in mind that foreign professors can leave their duties at certain periods only—viz., during the Easter recess and the months of August and September,—and that British scientific men, especially those residing in London, are generally absent during these latter months?

2. By what method can the design of the Congress be best carried into effect, whether by the appointment of an Executive Council to organise the details, subject to the approval of the General Committee of Delegates, or in what other way?

3. What branches of medical science should be comprised in the subjects to be discussed at the Congress?

4. How are funds to be obtained for defraying the expenses of the Congress?

Dr. Bennett was requested to take the chair, and having briefly explained the purpose of the meeting, letters were read excusing the absence of certain delegates.

The following resolutions were adopted:—

1. That an International Congress be held in London in 1881.

2. That it be held between the 4th and 15th of October.

3. That a General Committee be formed, to consist of the delegates, with power to add to their number, who shall have authority to make necessary arrangements for organising and working the Congress, and who shall report from time to time as may seem necessary to the delegates for the information of the bodies by whom they have been appointed.

4. That each member of the Congress pay a sum of one guinea.

5. It was resolved that the following be requested to form part of the General Committee:—W. Bowman, Esq., Dr. Matthews Duncan, Dr. William Farr, C.B., Sir William Gull, Bart., M.D., Professor Humphry, Sir William Jenner, Bart., K.C.B., M.D., Professor Lister, Wm. MacCormac, Esq., Sir James Paget, Bart., Professor Rolleston, Dr. Sieveking, John Simon, Esq., Dr. Storrar, Dr. Allen Thomson, Dr. Hermann Weber, and Erasmus Wilson, Esq.

After a vote of thanks to the chairman, and a request that Dr. Pitman would for the present continue to act as honorary secretary, the meeting separated.

THE NEW TREATMENT FOR CANCER.

THE remarkable statement made by Professor Clay, of Birmingham, in a paper which appeared in our columns last week on the "Treatment of Cancer by a new Method," has naturally excited great attention, and will doubtless induce hospital physicians and surgeons, and practitioners generally, to make a prompt trial of the remedy, which is declared to have achieved highly satisfactory results in the relief, if not also the *cure*, of a disease that has hitherto baffled treatment. The matter is evidently one of more than common moment to the profession and the public. It will be important, under these circumstances, to make sure that the drug employed is certainly what it professes to be. As a matter of fact, it is by no means easy to obtain Chian, or Cyprus turpentine. So long ago as the date of the publication of the earlier editions of Pereira's Materia Medica there was so much difficulty in procuring the substance that the profession was especially warned against the almost inevitable substitution of Venice or Canada turpentine, or some other terebinth of totally different properties, in dispensing of prescriptions, for Chian turpentine. Probably there is scarcely any of the true resin in the market at present, and only druggists who happen to possess a small forgotten store *can* supply it. We think it desirable to make this intimation for the sake of medical practitioners who may be anxious to try the remedy, but who are almost sure to be disappointed, unless they take more than ordinary measures to ensure accuracy. As Professor Clay stated in his paper, no other terebinth except the Chian has been known, or can be expected, to produce the effects which have followed its use in his cases. The public should also be cautioned against resorting to the remedy, without skilled medical advice and supervision; and very earnestly must they be made to understand that probably not a tithe of the medicine likely to be sold under the name of "Chian turpentine" during the next few months will be genuine. The caution given to the profession years ago by the then highest authority on the subject of pharmacy, at a time when there was no special demand for the drug, will be doubly necessary now, when nothing but the accident of having a small reserve on hand can enable any druggist to dispense it. It only remains to add that some of the received descriptions of *Terebinthina Chia* seu *Cypria* are so faulty that identification of the genuine drug will be attended with more than ordinary difficulty. It is the gum of a tree growing thirty or thirty-five feet in height, and is obtained by cutting crosswise with a hatchet the trunks of the largest trees. The yield is very small, "not exceeding eight or ten ounces" for each tree; so that it must be obvious that the bulk of the material sold under this designation at two or three shillings a pound is not genuine. Its consistency is that of honey, but it is more glutinous. The colour is greenish-yellow. It has an agreeable turpentine-like odour, combined with the odour of fennel or citron and jasmine. Its taste is very mild. By keeping it resinifies, and, we may add, loses some of its virtue. The coniferous turpentines, which do not possess its special qualities, are usually sold for it.

THE DISTRESS IN IRELAND.

A LETTER which appeared in *The Times* of the 27th ult. gave to the English public, for the first time, perhaps, an adequate conception of the distress now existing in Ireland. It related to a part only of the districts affected, but the general details may be pretty safely taken as applying to the distressed populations as a whole. The writer is Mr. J. H. Tuke, of the Society of Friends, who had witnessed much of the awful distress of the famine of 1846-47, and who has just concluded a fortnight's personal investigation of the state of things in County Donegal. He tells us that during this investigation he witnessed none of the dreadful scenes that were observed in 1846-47, but he leaves the impression on the mind that we may be very likely to underrate, from the absence of obvious distress, the extent to which real destitution exists. It is clear that a superficial view of the district he visited would lead to a very insufficient notion of the misery prevailing, and he is obviously not satisfied that the Poor-law authorities have fully apprehended the mischief existing or in store. He describes a large population simply kept alive on Indian wheat-meal issued by the relief committees, and this meal alone. "Kept alive" is the proper word to use; for the amount of food which the relief committees can give is insufficient, and indeed not designed, to keep an individual in good working condition. There are still several months to run before other sources for feeding than the relief societies and the Poor-law can be looked for. It is painful to think what may be the ultimate result upon the distressed people of the sort of chronic starvation to which they must be subjected during this period

Digitized by Google

At present there is singular freedom from serious disease in Donegal, but will this continue in the future? It behoves the Local Government Board for Ireland to look narrowly to this matter, lest, when least expected, there may be a sudden setting up of destructive disease in the most distressed districts. Mr. Tuke writes warmly of the excellent administration of the Duchess of Marlborough's fund, and the funds transmitted through Lord Mayor Sir F. Truscott.

ANCHYLOSTOMOSIS.

UNDER the rather misleading title of "Tunnel Trichinosis," the Geneva correspondent of a contemporary recently contributed some interesting particulars of an outbreak of parasitic disease, which we prefer to recognise by the term above given. The disease has nothing to do with flesh-worms, either as regards the habits of the parasites, or their mode of introduction into the human body. The affection attributed to the Gothard tunnel miners is common in warm countries, and has been variously called tropical anæmia, Dubini's worm-disease, Egyptian chlorosis, hypoæmia, and so forth. Its medical importance was first pointed out by Griesinger, who showed that the intestinal anchylostomes behaved like leeches, drawing the blood of their victims, and reducing them to an anæmic and perfectly helpless state. One of the best accounts of the disease as it occurs in Brazil was supplied by the late Dr. Wucherer, whose name is well known to our readers in connexion with filarial discoveries (*Ueber die Anchylostomumkrankheit*, &c.; *Deutsch. Arch. f. Klin. Med.*, 1872). According to the investigations of Leuckart and others, there seems to be no doubt that the disorder is contracted by drinking impure water, or rather by the swallowing of minute animalcules which are contained in the water, and which (as in the similar case of the guinea-worm larvæ) act as intermediate hosts or bearers. Dr. Cobbold's recent work on Parasites contains an abridged account of Wucherer's researches.

SPRING AILINGS.

THERE is much truth in the old prejudice against the spring as a season of special ailings and health troubles; and there was, and still is, a good deal to be said in favour of certain medical and hygienic precautions to be taken against these probable calamities. It is not only that, misled by the seeming "softness" of atmosphere and fitful gleams of sunshine, the unwary leave off their winter clothing too hastily, and take "cold"; even though this obvious danger may be escaped, there are disturbances of nervous system and disorderly states of the visceral organs, generally, which it is almost impossible to avoid and perilous to disregard. Without doubt the great bulk of the trouble experienced in living, and the pains that must be taken to battle with the enemies of health, are the fruits of our high civilisation. In a mode of existence more natural to the animal organism, not one tithe of what we now regard as necessary precautions would probably be required. It is, however, impossible to order the lives of the present generation in strict conformity with the laws of nature, and it remains to accept the situation with all its drawbacks. In face of this fact, those who would escape maladies incidental to the season, and which may, so to say, lay the foundations of grave and even permanent disease, must be content to undergo certain obvious inconveniences. Prominent among these is the prolonged wearing of thick and heavy clothes, a matter to which we drew attention on a recent occasion. Another burden that must be borne, more or less cheerfully, by the infirm of health, is the need of almost fidgety care to avoid sudden changes of temperature. At no other season is even a fairly strong person so likely to suffer what is termed a chill as now in the "spring weather." It may be too conjectural to hazard a belief that the atmosphere is at this season loaded with more than commonly active irritants, but experience attests the fact that those special irritations of the lining membrane of the throat, nasal cavities, and the air-passages, which are commonly classed under the popular term "influenza," are exceptionally prevalent. Disorders of the mucous membrane lining the stomach and intestinal canal are scarcely less general. All this points to a cause or to causes lying deeper than any mere variations of temperature, however potent this last-mentioned factor of morbid disturbances may be. A good safe maxim for the weakly during the next two months will be to live with more than ordinary watchfulness against the known perils of winter, and to add to this precaution a special carefulness to avoid close and impure atmospheres, badly or improperly cooked food, unfiltered water—in short, to stand on close guard against the assaults of disease, neglecting no symptom, however slight, which betokens an abnormal state of the organism. This is not a cheerful view of the season, but is one that is forced upon us by the prevalence of "ailings" and minor maladies, which in too many cases threaten to entail consequences of which it may be difficult to get rid. In the "good old days" materfamilias was on the alert with her "alteratives" and gentle aperients for the spring season. We are not sure the care bestowed was wasted, or that it has deservedly fallen into disuse.

DEATHS ON PLATFORMS AND WHEN SPEAKING.

SOME years ago Dr. George Johnson, of King's College, published a very interesting and important little paper which, so far as we are aware, has never received the attention it deserved, on the subject of giddiness and faintness while speaking, particularly when rising suddenly after long sitting, and immediately subsequent to a heavy meal. We have not the brochure at hand, but, speaking from memory, the explanation offered was to the effect that the special call made upon the lungs as vocal organs interfered with the respiratory oxygenation of the blood. A more rapid series of chest movements than continuous utterance renders possible is required, and to obviate this deficiency a few rapid breathings will generally suffice. This is an inadequate account of Dr. George Johnson's hypothesis, which we should be glad to see re-stated as a practical hint to inexperienced speakers. Our object in recalling the subject of this little paper is to point out that in an extension of the disorderly state described doubtless lies the cause of many a sudden death from exhaustion in the midst, or at the close of a speech. It is not easy for a weak heart to maintain the acceleration of pump-like movements required to propel the blood steadily through the head, and keep the current properly oxygenated.

SLIDING SEATS.

THAT Cambridge this year made so good a race against Oxford proved a surprise to many; certainly a victory by only four lengths did not justify the enormous odds laid on the winning crew. A close race, however, had been anticipated by many who had closely scrutinised the practice of the two crews, and had not given consideration only to the time test. Oxford, it is true, were the more taking crew, rowing a lively well-marked stroke, with a steady swing forward and clean finish, but it was noticed that the Cambridge men made better use of their legs in sliding, and had they pulled well together and avoided the "bucket forward," which has been such a fatal characteristic of many Cambridge crews, it is probable that the result would have been reversed. In the opinion of many well versed in aquatic matters the introduction of sliding seats will work a revolu-

Digitized by Google

tion in the art of rowing, and that the use of the "slide" will be still further developed. Already a celebrated Canadian sculler has considerably lengthened his sliding range, and the pace he is able to maintain has as yet been unsurpassed. The sliding seat throws more work on the muscles of the thigh and leg, especially the hamstring muscles, than was the case with fixed seats, without in any way diminishing the amount of work done by the muscles at the upper and back part of the chest. As more muscular work is brought into play by the sliding seat it will probably be found that the adoption of a slower rate of stroke will be most favourable for obtaining the advantage resulting from the exercise of that power. Should this prove to be the case, then the sliding seat will make rowing more truly an exercise than it is at present, by developing muscular work and lessening the strain thrown on the lungs and organs of circulation.

FAMILY PREDISPOSITION TO DIPHTHERIA.

THE local journals contain an exceedingly interesting *interim* report, by Dr. W. N. Thursfield, the medical officer of health for the Shropshire combined district, on an outbreak of diphtheria amongst children in the Ludlow Workhouse. The total number of children in the workhouse at the time of the outbreak was fifty-eight, but the disease at the date of the report had confined itself to those children who were attending the school. Among these children, forty-eight in number, there occurred between February 15th and March 15th thirty-two cases of diphtheria—or, to use Dr. Thursfield's term, contagious cynanche; for by far the greater number of the cases had been classed by the medical officer of the workhouse as sore-throat; six only, if we understand the report aright, having been designated by him as diphtheria. Dr. Thursfield infers that the disease had been imported into the workhouse, and he concludes that it had been disseminated there by the necessarily intimate association in school, &c., of the sick with the well in the earlier stages of the disease—possibly latrine contamination helping somewhat. The outbreak afforded a remarkable illustration of the predisposition which some families appear to have to contract diphtheria and to suffer from it severely. There were amongst the children in the school seven members of one family; all seven were affected with the disease, and three of them died, being the only three fatal cases of the thirty-two attacked.

"BURIED ALIVE."

THE bare possibility that an apparently deceased person may be "buried alive" is too terrible to contemplate without the keenest sense of horror. The fear of this contingency has been revived by some recent communications made to the French Academy of Medicine, on the subject of recovery by the prolonged use of artificial respiration, in cases of supposed death. It is difficult to avoid the inferential belief in a lurking danger when the value of any measure to restore life after seeming death is extolled. Probably, however, the only moral to be drawn from the success of artificial respiration, and like methods of treatment in cases of poisoning, is that extreme efforts should always be made to prolong life through the crisis of a poisoning or the states of apnœa and asphyxia caused by drowning or suffocation from any cause and by any agency. It is always *possible* that if the organic vitality can be maintained during a sufficiently long period the life of the body as a whole will be rekindled. Again, it is possible that certain modes of death occurring in the course of acute disease may admit of treatment. To such possibilities the medical profession is fully alive. The public should be aware that treatment of "the agony" has long formed a topic of special attention in the therapy of disease. There is, therefore, no room for new anxiety as to the point of being "buried alive." No medical man can be at a loss to determine whether an apparently deceased person is really dead. The only need of increased attention relates to cases of poisoning, suffocation, and such forms of death by hanging as do not fracture or dislocate the vertebræ of the neck. The utmost care requires to be taken in cases of capital punishment by hanging, but the prison surgeons are alive to the danger, and the public have no ground for disquietude or fresh alarm.

TYPHUS AND DIPHTHERIA IN RUSSIA.

DURING the week ending March 6th, 661 deaths were reported in St. Petersburg, and of these 14 per cent. were stated to have been caused by maculated typhus. The greater number of the deaths assigned to this cause were among children under five years of age, and next in order of frequency were among individuals from twenty to twenty-nine years of age.

A sum of 480,000 roubles has been placed by the Imperial Treasury at the command of the Minister of the Interior, for the purpose of giving assistance to the governments in which diphtheria is prevailing. Local resources, even with the assistance given by the Red Cross Society, have proved inadequate to meet necessary requirements in attempts to arrest the progress of the disease, and an appeal has been made by the governors of the infected provinces for help to the Imperial Government. To this appeal the special grant above-mentioned is the reply.

THE EFFECTS OF COLD.

M. COLIN has recently published some interesting researches on the effect of various refrigerating media on the temperature of the skin in animals. Those exposed to the action of cold air presented different effects according to the species of the animal, and examination showed that if the cold air lowered the temperature of the skin considerably they rapidly died, whereas if the cold did not effect a notable diminution in the temperature of the skin, it was well borne, and appeared even inoffensive. After establishing this law M. Colin confirmed it by exposing dogs and rabbits for a certain number of hours or days to the severe cold of last December. He found the temperature, even at the surface, remained nearly normal. Young animals, on the contrary, placed under the same conditions, became rapidly chilled and died, although their skin was well covered with hair, a proof that the latter is only one element in the question. If the animal, instead of being placed in the open air, is enclosed in a hut of ice, it manifests great power of resistance, and even after some hours may present a temperature almost equal to that existing at first. Placed in snow, there is a considerable chilling for some hours, followed by a strong reaction, so that after twelve hours the temperature scarcely differs from the normal, and even in the rabbit it presents a fall of only one degree. On the other hand, young animals placed in the snow die rapidly. Hence we must assume that, under these circumstances, as in the open air, the resistance to cold in the animal is due to different factors, among which the presence of a thick furry coat is an important, but by no means the only, one.

THE LATE DR. JOHN DEAKIN HEATON.

THIS distinguished physician, whose death occurred on the 29th ult., besides holding many important professional appointments, took great interest in social and educational movements in Leeds. He was Justice of the Peace for the West Riding and Chairman of the Council of the Yorkshire School of Science. He was also a member of the first school board for the borough of Leeds, and formerly President of the Philosophical and Literary Society.

WILLIAM FARR, C.B., M.D.

THE regulation C.B.—a distinction which is at once the smallest and least useful of honours—has been conferred on Dr. FARR. We congratulate a gentleman, whose merits are happily well-known to his profession, on this public recognition of his services, but we are no more grateful for the acknowledgment than for the ugly hall-marking sometimes graciously bestowed on pure gold.

URTICARIA.

M. VIDAL has published (*L'Union Médicale*, Feb. 24th) the results of an examination of a "wheal" excised during life from a patient suffering from urticaria. The superficial and deep network of vessels was found dilated and gorged with blood, without any alteration of their walls being discoverable. Both the bloodvessels and the lymphatic vessels were surrounded by leucocytes, which were also scattered through the whole thickness of the cutis, and massed together at certain points. A few were to be seen between the cells in the deepest layer of the epidermis. Here this structure was normal, but another piece of skin was excised from a wheal on which the epidermis had been raised in a vesicle. This vesicle contained a serous, albuminous liquid, and the débris of epithelial cells. In the middle layer the cells were vesicular, and those of the deeper layer granular. Leucocytes migrating among the cells in the deep layer of the epidermis were more numerous than in the other case.

M. Vidal remarks that from this pathological alteration we can see the nature of the morbid process. In a predisposed subject some internal or local cause excites the action of the vaso-motor nerves; this excitation is soon followed by contraction of the cutaneous capillaries, and this by their paresis and congestion, with retardation of the circulation. Hence, at the centre of the altered part, there is migration of leucocytes and serous effusion, the acute œdema causing the pale prominence. A similar lesion, a sort of acute œdema, may be produced artificially by injecting into the skin a few drops of water. What becomes of the leucocytes which have wandered out? Are they resorbed or are they carried towards the epidermic layer, as Biesiadecki suggests?

It will be observed that this theory ignores any participation of the muscular fibres of the skin, which has been assumed to account for the limitation of the œdema and consequent prominence of the wheal—a limitation which M. Vidal leaves unexplained.

A ROYAL DOCTOR.

IT is stated that the German Chancellor has caused the announcement to be made that His Royal Highness Duke Theodore of Bavaria, who recently took the degree of Doctor of Medicine at a German University, has received the certificate enabling him to practise as a surgeon without being required to undergo the additional examination to which intending practitioners are ordinarily liable under the German law. It may not be generally known that the Electoral Prince Charles, Count Palatine of the Rhine, was created a Doctor of Medicine at the University of Oxford just two hundred years ago—viz., 1680. The Duke of Montagu, who died in 1749, was a Fellow of the London College of Physicians, as was the Duke of Richmond, who died the following year.

THE CORONER FOR KENT.

WE are glad to hear that Dr. Theodore Maxwell, M.B. Cantab., of Woolwich, is a candidate for the coronership for the County of Kent, vacant by the death of Mr. Carttar. Dr. Maxwell's high professional standing ought to give him a strong claim with the freeholders of the county.

A CORRESPONDENT, in a letter dated Candahar, 2nd March 1880, states:—"Weather cool and pleasant, but has been very variable. Per cent. sick: Europeans 5·2, natives 7. Chest affections have been prevalent, and with natives sudden cerebral effusion has been observed in some instances. Since fall of rain and snow pneumonia has been less prevalent. Surgeon-Major R. H. Bolton, A.M.D., died on Feb. 27th, from abscess of the liver. He entered the service 30th September, 1863; was promoted Surgeon-Major 28th April, 1876. Surgeon McCartie, I.M.D., Med. Ch. 2nd B.C., was severely wounded on Feb. 29th. He was riding alone among the hills, and was fired at by a man supposed to be a hill robber; slug hit right clavicle and glancing off passed backwards, lodging deeply behind right shoulder, whence it was extracted; so far doing well. Preparations being made for advance, men of artillery have been put through a short course of bandaging and stretcher drill by Surgeon-Major Markey."

A LARGE meeting of medical students and others connected with St. Bartholomew's Hospital was held in one of the new lecture-rooms, on Wednesday, March 24th, to consider the advisability of forming a Medical Union Club, on the plan of the Oxford and Cambridge Unions, for medical men and students in London. The meeting was addressed by Mr. Luther Holden, President of the Royal College of Surgeons, and by Mr. Butlin. Mr. Savory also sent word to the meeting that the project, so far as it had been explained to him, received his warmest support and approval. A resolution was passed that the meeting considered it "desirable to establish a Medical Union Club."

MR. GEORGE HENRY JACKSON, house-surgeon of the Crumpsall Workhouse Infirmary, Manchester, contracted scarlet fever on Monday, the 23rd ult., which unfortunately terminated fatally on the Friday following. The deceased gentleman, thus cut off at the commencement of a promising career and in the midst of his beneficent exertions for the relief of the suffering poor, was educated at Liverpool, Edinburgh, and St. Thomas's, and obtained the licence of the Edinburgh College of Physicians and the membership of the London College of Surgeons only two years ago.

THE *Athenæum* states that the University of Aberdeen, stimulated by the recent move in advance made by her sister institutions in Edinburgh and Glasgow, has issued a report on certain changes and extensions which have been deemed desirable in the more northern seat of learning. Among these improvements are, the establishment of a botanical garden, the endowment of lectureships and higher scholarships, and the foundation of several new chairs, such as English Literature, History, and Pathological Anatomy.

A FAREWELL dinner to Surgeon-General H. H. Massey, C.B., on his retirement from the Army Medical Department, took place in the officers' mess-room, at Netley, on the 30th instant. Surgeon-General Massey has passed an honourable and distinguished career in the public service, and many brother officers and friends met together on the occasion to show their appreciation of the worth of his character, and to express their regrets at his quitting active employment in the army.

THE subject chosen by Dr. Symes Thompson for the course of lectures at Gresham College, to be delivered on April 6th and three following days, is "Digestion and Indigestion." The lectures are illustrated by diagrams, exhibited by means of the oxy-hydrogen lantern, are free to the public, and commence each evening at six o'clock. Lectures will also be delivered by the Gresham Professor of Medicine on October 12th, 13th, 14th, and 15th.

Digitized by Google

THE analyst for Limehouse, Dr. Rogers, has drawn attention to the fact that the inspectors under the Adulteration Act had become so well known to the shopkeepers of the district that it was almost impossible to obtain samples of food and drink which fairly represented the bulk. He was convinced that adulteration was carried on to a considerable extent, and wished the public would aid him in his duties by sending to him samples for analysis. Out of 700 articles tested, not one had been received from the public.

A MOTION was carried at a recent meeting of the Metropolitan Asylums District Board as follows:—"It being desirable to ascertain the relative percentage of non-pauper patients (if any) to pauper patients sent to and treated at the several fever and small-pox hospitals of the managers, the various hospital committees are hereby instructed to cause inquiries to be made at their respective establishments, and to report the results to the managers."

THE United College, including the faculties of Arts and Medicines, in the University of St. Andrews, is in difficulties. A few thousand pounds are needed to repair the deficiency of the exchequer, impoverished by the depreciation of rents. Surely the Medical alumni of this University are numerous, and should be active enough to give substantial help in the emergency.

MR. MICHAEL H. STAPLETON died at his residence in Mountjoy-place, Dublin, on the 30th ult. Deceased was a graduate in medicine of the University of Dublin, a Fellow of the Royal College of Surgeons in Ireland, and formerly an examiner in the latter institution.

A PROPOSITION has emanated from the Kensington guardians that Lock patients should be placed under the care of the managers of the Metropolitan Asylums Board, in the same way as other cases of an infectious character.

DR. GRATTAN, one of the oldest Fellows of the Irish College of Physicians, is a candidate for the representation of Kildare in Parliament; and Dr. Robert D. Lyons, of Dublin, has intimated his intention of contesting that city.

THE death is announced of Dr. W. P. Schimper, corresponding member of the Académie des Sciences, and the author of numerous important geological and botanical works.

HEALTH OF LARGE ENGLISH TOWNS.

TWELFTH WEEK OF 1880.

ENGLISH urban mortality shows a slight increase on the rates which prevailed during the fortnight ending 20th March. In twenty of the largest towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5140 births and 3144 deaths were registered last week. The births were 45, and the deaths 131, below the average weekly numbers during 1879. The deaths exceeded by 69 the slightly increased number of the preceding week. The annual death-rate in the twenty towns, which had steadily declined from 37·0 to 21·4 per 1000 in the six weeks ending March 13th, and was again 21·4 in the following week, rose to 21·9 last week. During the past twelve weeks the death-rate in these towns averaged 25·6 per 1000, against 23·8, 25·1, and 27·4 in the corresponding periods of 1877, 1878, and 1879. The lowest death-rates in the twenty towns last week were 11·7 in Brighton, 17·5 in Portsmouth, 19·3 in Leicester, and 19·9 in Wolverhampton. The rates in the other towns ranged upwards to 23·7 in Liverpool and in Norwich, 24·0 in Manchester, 26·7 in Nottingham, and 32·0, the highest rate during the week, in the borough of Plymouth. Measles continues to be exceptionally fatal in Plymouth, and during the twelve weeks of the current year has caused 122 deaths in the borough.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had risen to 476 in the week ending March 20th from the steadily declining numbers of the previous weeks, fell last week to 424; these included 160 from whooping-cough, 108 from scarlet fever, 80 from measles, and 37 from fever, chiefly enteric. The annual death-rate from these diseases averaged 3·0 per 1000 in the twenty towns. There were no deaths from the seven zymotic diseases registered in Brighton last week. The zymotic rate was but 0·4 per 1000 in Portsmouth, whereas it ranged upwards to 6·6 in Nottingham, and 8·4 in Plymouth. Whooping-cough showed the largest proportional fatality in Salford, London, and Newcastle-upon-Tyne; scarlet fever in Nottingham, Salford, Norwich, and Sunderland; and measles in Hull, Nottingham, and Plymouth. Fever, principally enteric, caused 18 deaths last week in London, 5 in Liverpool, and 4 in Sheffield. The 8 deaths from diphtheria in the twenty towns included 5 in London. Small-pox caused 4 more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had declined from 188 to 171 in the three preceding weeks, were 167 on Saturday last; 31 new cases of small-pox were admitted to these hospitals during last week, against 41 and 25 in the two previous weeks. The Highgate Small-pox Hospital contained 14 patients on Saturday last.

The fatality of lung diseases showed a slight increase last week. The deaths referred to diseases of the respiratory organs in London, which were 315 in each of the two preceding weeks, rose to 333 last week, but were no less than 141 below the corrected weekly average; 207 resulted from bronchitis, and 85 from pneumonia. The annual death-rate from diseases of this class in London last week was equal to 4·7 per 1000, against 5·9 from the same diseases in Liverpool.

Correspondence.

"Audi alteram partem."

THE SCOTCH UNIVERSITIES AND MEDICAL REFORM.

To the Editor of THE LANCET.

SIR,—I am glad to find that you give me credit for so much as is implied in your remark that, "if more closely cross-examined," I might "have come out as a very good medical reformer." I have always considered myself a reformer, medical and other, by hereditary as well as personal leanings, and it would be extremely contrary to all my best instincts to attack anything that was really of the nature of a reform, or to defend anything that was of the nature of an abuse. But I hold, none the less, that the so-called reforms set forth in the Government and the other medical Bills before the late Parliament, have been framed with a most reckless disregard of the interests of the Scotch universities; and by this I mean not the interest of the professors, but still more of the students, and of the education and discipline which are the very life of their system. And when it is considered that the extra-academical medical schools in Scotland are becoming every day more and more a part of the university system—inasmuch as their teaching is largely recognised by the universities, and their rivalry is such as to stimulate rather than to antagonise the university schools, to which, indeed, most of the extra-academical teachers look for their promotion when they attain distinction—I think I am not assuming too much in arguing that what is opposed to the interest of the one is also opposed to that of the other.

Now, Sir, I don't wish to boast. It is always unbecoming, and it is not a style of argument very likely to accomplish my present purposes. But surely I may appeal to THE LANCET as having on several occasions borne a very generous and most ample testimony to the efficiency of our Scotch schools, and particularly to the serious diligence with which the work both of teaching and of learning is

Digitized by Google

carried on in all the three teaching universities. The evidence given by Professor Turner on behalf of Edinburgh, and by Professor Struthers and myself on behalf of the other two, ought, I think, to be accepted as conclusive upon one point at least—viz., that our great prosperity since the Medical Act has not been the result of a lowering of our standard, either of discipline or of examination; but, on the contrary, of a great increase in the thoroughness and stringency of both. I venture to claim for the Scotch universities, for instance, to have been both earlier in adopting, and more resolute and systematic in carrying out, clinical and practical methods of examination and of instruction, than any of the London Boards. This distinction we owe, not to the personal qualifications of our teachers or examiners individually, but to the compactness of our system, which allows of all the means both of teaching and examination being available at one point, as it were; while in London they are distributed over a number of different centres; and it is notorious that the colleges in particular, in dealing with their large numbers of candidates, have found the greatest practical difficulties in even coming up to the demands of the Medical Council in this respect. We are able to accomplish what we do with comparatively little strain, because we have our laboratories, museums, hospitals, pathological departments, &c. &c., all subject to one set of conditions, in one locality, though not necessarily under one roof, or one set of authorities. It is the *university* which is at once the centre, and the regulating principle, round which all these means, so far as they subserve medical education, are grouped. It is the university which, by creating a stimulus and a demand for them, secures like advantages, indirectly, even for the extra-academical schools. And it is mainly owing to the university having within itself the powers of conferring a complete legal qualification, that these means and opportunities, alike for instruction and for examination, have arisen around it, and not as an adventitious growth around individual hospitals, having no relation, in the first instance, with any academic centre.

It is no part of my wish to make invidious comparisons, and I am very far from undervaluing, as all my friends in London and elsewhere know well, the splendid names and labours which have illustrated, and still illustrate, medical science in the metropolis. But the greater the eminence of these individual names, the more it becomes remarkable that a small and thinly-peopled country like Scotland, having a scattered population less than that of London alone, not to speak of England, should have been able to maintain in three separate centres of universities medical instruction, a system of elementary biological training on the one hand and of clinical and practical discipline on the other, which have so largely influenced professional thought and medical and surgical practice, even in the metropolis itself. Let any candid and impartial man cast his eye over the list of London celebrities, and ask himself how many of these have owed some part, or the whole, of their medical education to the Scotch universities. May we not fairly argue that a corrupt tree cannot bring forth such good fruits?

Nor is it any part of my purpose to disparage the English universities, least of all the University of London, the high-class medical degrees of which are justly valued and sought by the most eminent men in London itself and elsewhere. But it is important for my purpose to note that, with all this most legitimate prestige as regards its degrees, the University of London exercises almost no influence, directly, over the medical schools of London. It neither contributes to their status, nor strengthens their discipline, nor interferes with their curriculum of study, nor binds them in any way together in an organised whole. It leaves them, as it found them, what might almost be termed a fortuitous concourse of atoms. In other words, it is not a teaching university. I do not stop here to argue whether this is right or wrong in principle. My own opinion is that the University of London might do an unknown amount of good by affiliating the schools and taking some practical charge of them. But the fact remains that the system in Scotland has been from first to last *not* that of England, or of London; and it will not be denied that the three Scotch universities are at this moment exercising a far more widely diffused influence for good over the whole field of medical education in the profession at large than the University of London, or than all the four English universities taken together. This influence they owe, I maintain, entirely to the fact that they have been always so constituted as to have their degrees practically recognised, while the Medical Act of 1858 enabled them to give a complete and independent legal qualification to practise, and the Universities Act of 1859 raised the status of the Scotch medical degree generally, so as to represent a very varied, solid, and thorough medical training, which only the power of giving a complete legal qualification would have enabled them to exact from their students.

If any of your readers calling themselves medical reformers are ignorant of these facts, or unwilling to acknowledge them, I will respectfully ask them to do one of two things—viz., either to study carefully and impartially the evidence given before the Committee on the Medical Bills on behalf of the Scotch universities, or, still better, to come down to Scotland and see with their own eyes what we are doing, both as regards teaching and examination. But that many English medical reformers and legislators are utterly ignorant of the facts with which they have to do, so far at least as reforms affecting the Scotch universities are concerned, is too manifest to require proof. And it is not at all surprising that it should be so. For while the Scotch system of university medical education is, allowing for national differences, in the main that of almost all Europe, the English system is a thing entirely and absolutely of English growth, and differing from that of all other countries under the sun; and the *double* qualification (which I agree with you in thinking ought to be not *double*, but *single*, and *complete*), is the index, or at least one of the notes, of the difference. In England the medical profession has gradually emerged out of trading guilds, and royal monopolies of practice, conceded to incorporated bodies of physicians, surgeons, and apothecaries. These have all of them done good service in lifting the profession out of the dust, but they have failed to give it, broadly speaking, an academic status. The universities were too high-minded, too expensive, and too socially exclusive, for this work. In Scotland the universities condescended to the wants of humanity in a practical way; condescended, perhaps, too much in the first instance. But they have nevertheless infused into the whole of the medical schools an academic element, which, now that it has been strengthened and purified from abuses by time and the useful legislation of 1859, is an influence of the first importance in all the medical education of the united kingdom. The new legislation proposed, under the name of medical reform, by Englishmen for England, may or may not be suitable for remedying the errors and deficiencies of their "double qualifications;" but, as applied to the Scotch universities, it would be a wholly retrograde measure of "medical reform;" as it would rob them of a legal privilege which is already carefully guarded by statute against abuse, and is the very keystone of their whole system.

To *compel*, by law, our Glasgow University students, for example, to seek a licence to practise elsewhere than in Glasgow, and from a body of examiners wholly unconnected with the university, is practically to disturb and distract mischievously the course of their studies, to relax their academic discipline, and to turn them in the last years of their education from hospital and practical work, to attending grinders' classes, and getting up grinders' books. The regular academic training and examinations in Glasgow have not this effect, at least to any considerable extent, because they are carefully founded on what experience, as between teacher and pupil, has shown to be the most practical and most instructive; and the clinical examinations in particular react on the hospital training, so as to give it a thoroughness and regularity which, so far as I know, are unattainable except in a university, which is also a large medical school. The conjoint board system takes no note of these delicate adjustments, delicate alike for the teacher and the pupil, and lying at the very root of the Scotch university system. It simply assumes that all manner of candidates for a medical licence can be uniformly tested by a board as you test herrings in a barrel—i.e., so as to eliminate all that are below a certain minimum; or, as Mr. Simon, I think, put it more politely perhaps, but not more truly, as sovereigns are minted so as to secure a certain average of weight and quality of gold. My reply to this illustration is that it omits altogether to take count of one little circumstance. The herring is there, and the gold is there; the one has been drawn out of the sea, and the other out of the mine; but in neither case has the assaying, or the branding, or the minting any effect whatever on the growth or the production of the article. But the medical graduate or licentiate is the complex re-

Digitized by Google

sult of a costly and elaborate system of discipline applied to the mind variously over many years, and the whole course of that discipline is apt to be controlled and regulated by the nature of the tests applied at the end of it. It is not a question of minimum, but a question of the reflex influence of the test. Or, as I said in the Committee, it is not the *minting* of the student, but the *making* of him, that is really of the greatest consequence to all of us, and to the public.

You say, very justly, that raising the base of a pyramid will not diminish the height of the pyramid. Certainly not, if the pyramid remains secure. But raising the base of a pyramid in a rash and inconsiderate way may shake the whole edifice from top to bottom.

I adhere, however, to the general idea of the suggestion I made in my evidence, and which is so far in conformity with the principle, if not of the details, of the modified *Staats Examen* now existing in Germany. If there must be a system of central control over all examinations, emanating from the Medical Council or from any other authority, let the examiners be sent to Glasgow to co-operate with ours, instead of compelling our students to pass a double series of examinations. It is surely more reasonable that the three or four or half-a-dozen men wanted for this purpose should go to reinforce the university examiners, and aid them with their opinion, than that 80, 100, or 150 candidates should be obliged to keep in view two distinct series of examinations where one would suffice. Further, I expect that the board examiners would learn something from us, as well as we something from them, which would be a material advantage, and would enable them to transfer to other examinations the experience gained in ours, and to ours the suggestions arising from other examinations. Finally, I have personally no objection to binding the university, under these circumstances, not to pass, as a graduate, any candidate whom the board examiners would reject. A minimum in this shape would, indeed, do us no harm. But if, this proposal being made, you[1] do not fairly consider it, and endeavour to give it effect, then I say you are bent not on raising the base of the pyramid, but on demolishing the pyramid; not on strengthening the Scotch universities for doing their useful and necessary work, but on destroying that legal position which enables them to do their work effectually; not on medical reform, in any genuine sense of the word, but on a mere arbitrary programme which a certain number of English authorities have agreed upon as suitable for England, and which you insist on our accepting in spite of both reason and common-sense.

I am, Sir, yours, &c.,

Edinburgh, March, 1880. W. T. GAIRDNER.

SALICYLATE OF QUININE.

To the Editor of THE LANCET.

SIR,—Salicin, salicylic acid, and salicylate of soda have obtained a reputation in the treatment of rheumatism. But so far as I have been able to ascertain no notice has yet been taken, in this country at all events, of another salicylate, which seems likely to secure a high place in the treatment of that malady—I mean salicylate of quinine.

The first mention I had of it was made to me in a letter by a patient resident with her family in Paris during the past winter. One of her sons had a sharp attack of rheumatic gout. Salicylate of quinine was prescribed for him, and she wrote of the effects as wonderfully rapid and satisfactory. Ten days ago she returned to London and sent for me to attend one of her family, who had suffered severely in their rough passage across the Channel. For three days previously I had been suffering from rheumatism in the left knee and thigh. It had steadily increased to such an extent that I could hardly walk at all; and when I sat down it cost me much pain and difficulty to rise up, and still more to make any progress. My movements were awkward and distressing to myself and to lookers-on. My good friend was very sympathetic. In her usual kind and practical way she ordered me "home to bed," and early next day, as soon as she could get to her boxes, she sent me a note with a bottle of the salicylate of quinine, which she had brought over with her. Pressing engagements prevented me remaining in bed that forenoon. But by four o'clock in the afternoon I was dead beat, and quite incapable of further work. Between four and five I retired to bed. For two days previously I had fever on me, which had gradually increased, and now my temperature stood at 101°. My usual temperature is 97·5° to 98.° I at once took a dose of salicylate of quinine—twenty centigrammes—as directed on the bottle. In bed I could not move my leg or turn myself without the greatest difficulty and suffering. During the night I perspired freely. Next morning, Feb. 22nd, there were still fever and pain, but the temperature was considerably less. All that day I remained in bed, and I took three doses of salicylate of quinine at intervals of four hours. In the evening and during the night I felt I could move myself altogether with greater ease, and I had a quiet good night. Next morning, Feb. 23rd, I felt completely relieved. To my astonishment (for this was not my first attack), I got out of bed and walked across the bedroom without the slightest limp. The posterior muscles of my thigh certainly felt sore as if they had been severely strained and bruised, but I felt as able for my work that day as if nothing had happened, and I did a long day's work.

On Tuesday, the 24th, I felt really quite well, only, as I was informed, looking very pale and thin. By this time I had finished all my stock of salicylate of quinine, and I did not think it necessary to take any more. However, in three or four days after, I began to feel again a slight soreness and stiffness of the same muscles. This seemed to confirm the necessity for the caution which my kind benefactress laid on me at the first—namely, not to discontinue the medicine too suddenly.

Salicylate of quinine, though not usually employed hitherto in London, is to be procured. The difficulty I have found is to get it easily dissolved, and kept in solution. Mons. L. Midy, a pharmacien of Paris, 113, Faubourg St. Honoré, has made an elegant preparation of this drug. It is one I have used, and I can recommend it. But I have no doubt our expert London chemists will be able also to master any difficulty that may appear at first sight to exist.

I think this is an opportune moment wherein at once to bring the evidently valuable drug to the notice of the profession.

I remain, Sir, your obedient servant,

ARCHIBALD HEWAN, M.D.

Chester-square, March, 1880.

TYPHOID FEVER IN THE EAST.

To the Editor of THE LANCET.

SIR,—The enclosed letter is interesting in reference to the etiology of typhoid fever in the East and tropics. As you have published others on the same subject, perhaps you will kindly give this a place also.

I am, Sir, yours truly,

J. FAYRER.

Granville-place, Portman-square, W., March 16th, 1880.

Calcutta, Feb. 25th, 1880.

DEAR SIR,—I too have long been of opinion that typhoid fever may have origin in other causes than the filth to which in most cases it is rightly assigned. Or, as I have frequently expressed it, that the problem—given a fever, required a stench—is not universally capable of being solved, and this more especially in tropical and subtropical climates. During a service of twenty-seven years I have treated typhoid fever in the Mauritius, Barbadoes, and Bermudas, and this conviction has gained strength as my experience has extended. I was much pleased to see it obtain the support of your authority.

I have often felt tempted to express my opinion in the medical periodicals, but have been deterred by the difficulty of proving a negative, or of obtaining sufficiently exhaustive evidence to render the position practically unassailable.

Being now separated from my notes, and not having by me a copy of my official report on a severe visitation of typhoid fever from which my late regiment (1st Battalion, 15th Foot) suffered in Bermuda in 1868-69, I can only give from memory a general outline of the facts, which, however, may possess some interest.

The regiment was ordered from New Brunswick to Bermuda in April, 1868, as supernumerary to the garrison, to be employed on the works (fortifications). When we left New Brunswick the frost was still on the ground; in four days we

[1] I trust it is scarcely necessary to explain that I do not mean by *you* the Editor of THE LANCET, but the originators and promoters of the Medical Bills.—W. T. G.

Digitized by Google

were in the commencement of a very hot season in Bermuda. A portion of the regiment was encamped. The head-quarters was in barracks at St. George's. Dysenteric cases shortly appeared in both parties, followed by typhoid fever in the companies under canvas, and this so severely that the encampment had to be broken up, and the men were put into barracks at Boaz Island, and not employed on the works. The fever then ceased.

At a later period another party were encamped at another part of the islands, relieving a party of the 61st Regiment. The 61st party had been free from fever. They were acclimatised. Fever (typhoid) broke out again so severely in my regiment that the party had to be withdrawn. About the same time it broke out at head-quarters, and was very severe. I stated in my report my inability to trace it to any defective sanitary arrangement.

In the encampments the dry-earth system of conservancy was adopted. The water used was rain, collected in tanks, removed from any possible source of pollution. At head-quarters the tanks were of iron. Every possible attention was paid to the sanitary condition of camps and quarters. The 61st acclimatised party had been free from fever with the same arrangements in the same encampment. At head-quarters the barracks were favourably situated, above and outside the town, and were exposed to wind from every quarter. The town, with its narrow lanes, dense population, cut off from the wind on two sides, by the hill on which the barracks stood, and with certainly inferior sanitary arrangements, was at this time free from typhoid fever.

The only universally applicable explanation of these cases appeared to me to be "climatic causes affecting new-comers." A very sad case in support of this view occurred on the relief of my regiment in 1870. A young officer of the relieving regiment, lately married, took a detached cottage near my own house. It had been occupied for more than two years, to my knowledge, by an officer of engineers, his wife and child, without any case of fever. The *new-comers* had not been in it two months before this officer lost his young wife of typhoid fever.

I remain, dear Sir, faithfully yours,

JOHNSTON FERGUSON, Surgeon-Major.

Sir Joseph Fayrer, K.C.S.I.

TWO CASES OF VACCINATION WITH LYMPH FROM THE CALF.

To the Editor of THE LANCET.

SIR,—As the question of the introduction of calf lymph for vaccination is now being discussed, the report of the two following cases, which occurred in my practice within the last three weeks, may prove instructive and worthy of perusal.

1. On Feb. 20th, 1880, I vaccinated a healthy male child of Mrs. F——, aged three months. It was small, being a seven-months' child. As the mother objected to both arms being scarified, three marks were placed on one arm, the ordinary cross scarifications being made, and the lymph from the tube blown upon the lancet and rubbed in. That day week, on calling, I found that each of the three places had taken, the usual groups of vesicles resulting—in one mark remaining distinct, in the other two running into one large pock. The marks were in no way unusual, free from all areola, and could be described as good vaccine vesicles. I took several tubes for future use, and learned from the mother that the child had been very well, save the night before, when it was fretful and slightly feverish. The vesicles followed the ordinary course, drying and scabbing without any unusual irritation, and leaving good marks.

2. On Feb. 25th, a tube of the same lymph was used to vaccinate the male child of Mrs. A——, aged six months. This was stronger and healthier than the above, being born at full time, and the first child of its parents. The arm was scarified in exactly the same way as before, three marks being made, and the blood scarcely drawn in any one of the places. That day week, March 3rd, on calling I found one fair vesicle formed, the other two being small and partially scabbed over. A slight erythematous blush was noticed around the spots, but not more than a marked areola. On inquiry the mother informed me that the vesicles had been accidentally rubbed the day before, the lymph escaping. I was somewhat dissatisfied at the result, and warned her that the inflammation and small pocks were the result of the vesicles being injured and ruptured the day before.

March 5th.—Sent for to find the child in great pain, crying for half an hour at a time, with the arm swollen and erysipelatous at the elbow and on the contiguous parts above and below. Area of the vesicles free, but disease was evidently spreading down the forearm. Ordered lead and opium lotion, with compound chalk powder.

March 7th.—Pain unrelieved, arm swollen to twice its usual size and erysipelatous to the wrist. No action about the vesicles; child feverish and refusing its food. Ordered drop doses of laudanum, and continued lead lotion. In evening fingers contracted, with swelling of hand. Inflammation somewhat less; the pain was greatly relieved; the child seemed better, taking the breast.

March 10th.—Erysipelas reappeared at the site of the vesicles, spreading up on to the shoulder; the child had some difficulty in swallowing, and the neck seemed painful and stiff on the affected side. Arm still much swollen and inflamed. Ordered the limb to be covered with flour, and wrapped carefully in cotton wadding, and gave child minim and a half doses of tincture of steel, with half minim of tincture of opium, and a calomel powder, as the bowels were confined. Without following out the case daily, I may say that for the next four days the disease remained stationary, appearing now on the forearm and again on the shoulder, the swelling being undiminished, and the tenderness increasing.

On the 14th the arm was less red, but at the elbow swollen and very tender, at an indurated spot on the inner aspect of the forearm. The child's general health was, however, better, the bowels acted well, and he took his food. A bread and hop poultice was applied, and a saline given. Hardness on the following day was felt above the bend of the elbow on its inner side, the forearm being softer and smaller. Under poulticing these suspicious spots gradually passed away, the vesicles, which at one time were large, ulcerated, unhealthy sores, dried up and formed scabs. The arm decreased rapidly in size, and on the 18th of March was desquamating and of natural colour. The child is now well. The lymph was obtained in tubes from Messrs. Corbyn and Co., of High Holborn. It is not often that two cases occur at the same time offering such points of interest as the above, and although the results of the first case were very satisfactory, I have never seen from ordinary vaccinations (and as public vaccinator I have had some experience) so severe an attack of erysipelas as resulted in Case 2.

I remain, Sir, your obedient servant,

Hailsham, March 22nd, 1880. J. H. BOGLE, M.B.

TREATMENT OF CANCER BY CHIAN TURPENTINE.

To the Editor of THE LANCET.

SIR,—The valuable and exceedingly interesting paper of Professor Clay in THE LANCET of March 27th on the treatment of cancer of the uterus by the internal administration of Chian turpentine is certain to lead to a sudden and large demand for this substance.

Under these circumstances it does not seem to me impertinent to remind the profession that genuine Chian turpentine is hardly to be met with at present in the English market. What is sold as such is either greatly adulterated or a wholly factitious article manufactured from black resin, Canada balsam, and the essential oils of fennel and juniper.

Many disappointments and discrepancies may perhaps be avoided by keeping this fact in mind in ordering, and exacting an assurance from the wholesale chemist that what is supplied is, the genuine, unsophisticated, Levantine product. I am, Sir, yours, &c.,

Blackpool, March 28th, 1880. WM. HARDMAN.

*** See our remarks on this subject elsewhere.—ED. L.

THE NAVAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—It appears to me that some at least of your suggestions in regard to the Medical Service of the Royal Navy would only tend to make complication more complicated. I speak more particularly of the number of examinations a medical man would have to undergo after he has become fully qualified to practise his profession.

Digitized by Google

Take, for example, an ordinary College and Hall man. He has to pass separately his "Prelim.," first Hall, first College, final Hall, and final College—*five* in all; then if he enters the Navy he will have to pass first at the Admiralty, then go to Netley for a term, at the end of which another examination confronts him—making *seven* before he is fairly launched in the service; next, after four or six years' service, he has to go back to "school" at Netley, attend a course of lectures and pass another examination; and after ten or twelve years more he passes his "final," and has done with examinations (at least as far as this world is concerned)—making a total of *nine*.

If by this means you think you will benefit either the profession or the Navy, all I can say is I don't agree with you; on the contrary, I believe that a man qualified to practise medicine and surgery is fit to do his duty in any part of the world, assisted by a good library, so that he may look up any particular diseases incidental to certain climates, which any one would naturally do.

In conclusion I will remark, that there are men of retentive memories, but possessing few other faculties, who would pass examination after examination and be of as little use afterwards as they were before. Original genius is rarely the property of the dull plodder, for as a rule he is little more than a copy of the books he has read.

I remain, Sir, yours truly,

CANDIDATE.

*** We have not advised any additional examinations. As the matter stands, there are those which every student must undergo for qualification to practise medicine and surgery; then for the public services there are the competitive examinations for entry to, and after special tuition at, Netley. Beyond these there is in the navy the final examination for promotion to the rank of staff-surgeon. Relying on the opinions of officers of standing in the service, we believe it would not be judicious to relax the present regulation for the last, of which it is even said that, had it existed in the army also, the greatest of all late difficulties in that service would have been precluded. In order to give the navy surgeon the best means of preparation for it, we have suggested that he should, while on full pay, be allowed to attend a Netley course, which at mature age would be, as we think, of still greater value than the actual course before admission. We would recommend candidates not to dwell too much on the requirements to afford proof of having maintained their professional knowledge, for at least a few years, up to the standard exacted from them at the termination of their pupilage, and to remember that the best of practitioners never cease to be students.—ED. L.

To the Editor of THE LANCET.

SIR,—The Naval Medical Service is now in the very perils of parturition, and THE LANCET is acting the part of a kind and skilful accoucheur. It is to be hoped that more than a "mus ridiculus" will be born. There is one point that particularly interests me, and all of my rank, and that is, that in carrying into effect this compulsory retirement of fleet surgeons at fifty-five instead of sixty years of age, we may not be treated in the same arbitrary and uncompensated style as our seniors were in 1875, forming a blot on the administration that undermined all confidence of thinking officers in its good faith. Hoping you will afford a constant reader room for this,

I remain, Sir, yours, &c.,

ONE OF THEM.

TRANSVERSE DEPRESSIONS ON THE NAILS.

To the Editor of THE LANCET.

SIR,—I am glad the communications of Dr. Thin and Dr. Dyce Duckworth have drawn attention to the clinical and forensic importance of transverse depressions on the nails. Many years ago Professor Sanders showed me these furrows in the Edinburgh Royal Infirmary, and I have been accustomed since to look for them in the patients who have come under my care. I agree with Dr. Duckworth that "there is a rather more rapid formation of nail than that of two complete growths in a year." From my own observations I should say that from three to four months are usually occupied in the passage of a furrow from the lunula to the end of the nail. These grooves are very common. They are sometimes to be seen on all the finger-nails; often they occur only on the thumb-nails. If a person's nails be free from transverse furrows, we may conclude, almost with absolute certainty, that he has not had a serious illness in the last three or four months. I have found three or four of these depressions, equidistant and parallel, on the thumb-nails of women who are the subjects of dysmenorrhœa—a furrow marking each painful "period."

I am, Sir, your obedient servant,

JAMES SAWYER, M.D. LOND.

Birmingham, March 26th, 1880.

PARIS.

(From our own Correspondent.)

SINCE the beginning of the present year eight hundred persons have died of small-pox in Paris, and this number represents a twentieth of the whole mortality. At present the epidemic shows no signs of abatement, the week ending March 18th giving about the same average in an aggregate of sixty-six deaths from this cause. A more opportune moment could scarcely have been chosen for the presentation of a Bill to make vaccination compulsory in France, and if the Parliament sanctions the *projet de loi* which has been placed on the table of the Chamber of Deputies by Dr. Lionville, the epidemic will have been a means to the end of making France the best vaccinated country in the world. The proposed law consists of ten clauses, which are as follows:—1. Vaccination is compulsory; it must be performed during the first six months of existence. 2. Revaccination is compulsory every ten years; in the 10th, 20th, 30th, 40th, 50th years of the person's age. 3. When a birth is registered, a vaccination paper (*bulletin de vaccine*) will be given to the parties registering, and this must be returned within six months, stating the result of the vaccination, and signed by a medical practitioner of the locality. The signature must be *visé* by the authorities (*légalisée*). 4. The vaccination paper must be shown to the registrar every ten years, and must bear the mention of the subsequent revaccinations. 5. Parents and guardians as well as those convicted of infringing the 3rd and 4th Clauses of this Act, are liable to a fine of from 1 to 25 francs, and on a second conviction to a fine of from 25 to 100 francs. 6. This vaccination paper must be presented before entrance into a primary, secondary, or higher school, and also for the army and civil services. 7. Infractions of the preceding clause are punishable by Clause 5. 8. The registrars shall make a list of those whose certificate is in default each year, and this list shall be sent in to the magistrates, and the offenders prosecuted. 9. A *règlement d'administration publique* shall provide for the execution of this law, conformably to the royal ordinance of December 20th, 1820, the Ministerial decree of July 16th, 1823, and the decrees of August 10th, 1848, and October 7th, 1879. 10. The present law shall come into force within a year after its enactment. It is probable that some parts of this Act will be modified in the Chamber. It will be difficult, for instance, to apply the 4th Clause in its full rigour to those not revaccinated who have changed their place of residence, and more especially in large towns where it is of greater importance that no material for small-pox should be found. There is no doubt, however, that the fate of the proposed law will be decided on its merits. In sanitary matters the French are slow—much behind some of her neighbours; but when matters are under consideration they are generally referred to and decided by competent authority, unmindful of the agitation raised by leagues and societies of mischievous fanatics, too often mistaken in England for public opinion.

In spite of the Academy of Medicine, which officially condemned the project a few years since, the municipal authorities have decided to establish a model nursery in connexion with the Children's Hospital to experiment the system of *allaitement artificiel*, and the direction of this will be given to Professor Parrot. The high infantile mortality of Paris is a standing scandal. The number of deaths per annum amongst

Digitized by Google

children under a year old in Paris averages 338 per 1000, but last week it attained the proportion of 585 per 1000, mostly due to gastro-enteritis and "athrepsia." These are in many instances the technical expressions for improper and insufficient feeding, and it will be well if the lower classes can be taught that children who cannot suck may still be able to swallow.

At the Academy of Medicine it was announced that the widow of the late Professor Louis had left by will a sum sufficient to found a triennial prize of 8000 francs. This is to be awarded for work in therapeutics. Dr. Clement of Lyons claims to have used a cooling apparatus for the last three years analogous to that described by M. Dumontpallier, and which was the subject of an article in THE LANCET of the 27th of March, but, according to the secretary of the Academy, who has examined into the matter, there are essential differences between the apparatus of the two claimants. Apropos of a communication made at the preceding meeting by M. Jules Guérin, about a lady whose triceps femoralis was ruptured, and who, after having been treated by a distinguished surgeon in Paris by mistake for arthritis, consulted him, and had an elastic appliance fitted, which restored the power of extension, M. Tillaux said that he had seen the lady in question for arthritis, and maintained the correctness of this diagnosis. M. Guéneau de Mussy added, that it had come to his knowledge through the attending physician, that the patient was incapable of walking whilst in M. Guérin's apparatus, but since she had taken it off and resorted to *massage* she has been able to walk. To which M. Guérin replied, that she cannot, nor will she ever walk again. This is a specimen of an Academy "discussion."

Obituary.

HENRY EDWARD FRIPP, M.D., M.R.C.P.

THE medical profession of Bristol has sustained a severe loss by the sudden death, on March 23rd, of Dr. Henry Edward Fripp, in his sixty fourth year. While standing by the bedside of a patient on the previous night Dr. Fripp was seized with hemiplegia, which proved fatal within a few hours by the extension of the hæmorrhage towards the medulla.

Dr. Fripp was born in 1816, and passed through his curriculum at the Bristol Medical School, being a pupil of the late Dr. Symonds, at the Bristol General Hospital. In 1838 he became a member of the Royal College of Surgeons, and then began practice in Wales as medical officer to the iron works at Ynisceedwyn, near Swansea. Shortly after this he went to Germany as medical officer to the iron works at Nisterthal, in the Duchy of Nassau. By nature a mechanical genius, Dr. Fripp took so great an interest in these works that, in addition to his professional responsibilities, at the request of the directors, he accepted the office of chief engineer, and held this post till 1848, when these works were closed owing to disturbances consequent upon the unsettled state of the political atmosphere. After this Dr. Fripp spent some years on the Continent in medical and scientific study and research, and in 1855 took the degree of M.D. at Würtzburg. While abroad he worked for some considerable time under Kölliker. In 1836 he obtained the Membership of the Royal College of Physicians of London, and settled in Clifton as a physician. He was soon elected physician to the Bristol General Hospital, and held this post till 1873, when he was made consulting physician to this institution. He occupied the chair of physiology in the Bristol Medical School from 1857 to 1869.

Dr. Fripp was an active member of the various local medical and scientific societies. For some years he was president of the Bristol Naturalists' Society, in the proceedings of which Society he always manifested great interest and took a leading part. He also held the post of president of the Bristol Microscopical Society. During the year 1878–79 he was president of the Bristol Medico-Chirurgical Society, and his inaugural address was a learned dissertation on "The Doctrine of *Contagium Vivum* in its Relation to Parasitic Disease." Under his auspices the first volume of the Transactions of this Society was published.

Dr. Fripp was well known for his great scientific learning and practical knowledge. A most able physiologist and pathologist, there were probably but few men in this country whose acquaintance with the microscope was so thorough. The following list of some of his published papers will best indicate the nature of his knowledge of this instrument—communicated to the Bristol Naturalists' Society: "On the Physiological Limits of Microscopic Vision;" "On Aperture, and Definition of the Microscope Object-Glass;" "On the Limits of the Optical Capacity of the Microscope" (translated from Helmholtz); "Is there a Science of Microscopy?" In his hands the microscope was not merely an instrument by means of which certain things could be demonstrated, but he brought to bear upon it a profound knowledge of the physical laws which govern and modify and limit its revelations. In the department of Natural History Dr. Fripp was an original and enthusiastic writer. Amongst his various papers are the following (communicated to the Bristol Naturalists' Society): "On Insect Anatomy," "On Insect Sounds," "On the Faculty of Hearing and the Tympanic Organ of certain Orthoptera."

Dr. Fripp was a great lover of music, and was himself an accomplished musician, and as an illustration of his mechanical skill it may be mentioned that he possessed an organ which he had himself built.

As a physician Dr. Fripp had a well-earned reputation for skill and acumen. Amongst the members of his profession his uniform genial kindliness made him a universal favourite, and to his patients he was not only the able physician in whose hands they placed themselves with the utmost confidence, but the beloved friend to whom they looked and on whom they relied.

JAMES HINDMARSH BARNES, L.R.C.P. EDIN., M.R.C.S. ENG.

THE lamented death of this esteemed practitioner took place on the 19th ult. at his residence, Pembroke-place, Liverpool, at the early age of forty-seven. His fatal illness was the result of blood-poisoning, contracted thirteen years ago while attending professionally upon a syphilitic patient at the workhouse infirmary, and which not only prevented him from following his profession, in which he was taking a foremost place, but, in spite of the advice and treatment of some of the leading medical men of the day, caused him for years to endure great physical suffering. He was seen at various times by Mr. Jonathan Hutchinson, Dr. Hughlings Jackson, Mr. Berkeley Hill, and others, all of whom were much interested in his case. The deceased gentleman published a pamphlet describing the various symptoms of his disorder, which was read before the Medical Society at Liverpool; and in 1874 he was appointed superintendent registrar of Liverpool, as some compensation for the injuries he had received, which post he has only retained five years. Mr. Barnes was the second son of a medical man at Bath, and for some time held the post of consulting surgeon to the workhouse, succeeding Dr. Fletcher in that office. He was much respected not only for his professional ability, but for his genial and intellectual qualities.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on March 25th:—

Honman, Andrew, Weymouth-street.
Newnham, Ernest Edmund, Charing-cross Hospital.
Permewan, Arthur Edward, Redruth.
Rout, Charles, Silwood-place, South Kensington.

The following gentlemen on the same day passed the Primary Professional Examination:—

Joseph Adams, Edinburgh Royal Infirmary; Charles Robert Crane, Charing-cross Hospital.

THE Hospital for Imbeciles and Lunatics at Darenth will, it is announced, be opened for the reception of patients some time in the present month.

SMALL-POX is said to have appeared in Aberdeen. The cases already reported, three in number, have been removed to the hospital for infectious diseases in the town.

DR. G. R. BARNES, medical officer of the Ewell district of the Epsom Union, has been awarded a gratuity of £10 10s. for extra services consequent on the recent fever epidemic at Ewell.

Digitized by Google

THE salary of Dr. Pitt, medical officer of District No. 1 of St. George's in the East, has been increased to £280, in consideration of the additional area included in his district.

AN examination for cadetships at the Royal Military College, Sandhurst, is announced to take place at the University of London, on Monday, July 5th, and following days, the first day being devoted to the medical examination of the candidates.

IN the North-West provinces and Oudh during the past year (says the *Bombay Gazette*), 1051 persons and 7214 head of cattle were killed by wild animals, and 3168 persons died from snake bites. Wolves and leopards were most destructive, both among men and cattle. The total number of wild animals returned as destroyed is 4495, and the number of snakes killed is set down as 1697, the amount paid in rewards for their destruction being about Rs. 11,000. The number of snakes returned as destroyed (1697) gives a very imperfect representation of the number actually killed.

SUNDAY LECTURE SOCIETY.—In connexion with this society, a lecture is announced to be delivered at St. George's Hall, Langham-place, on April 4th, at four o'clock, by Dr. Spencer Cobbold, F.R.S., on "Trichinosis, and on the dangers arising from the consumption of Flesh Food."

BRISTOL EYE HOSPITAL.—The report of this Charity, read at the sixty-ninth annual meeting of its friends and subscribers, stated the number of fresh cases treated during the past year as 2592, 2535 out-patients and 57 in-patients. The total number of recipients of the benefits of the hospital since its establishment amounted to 83,514.

THE ABERDEEN HOSPITAL FOR INCURABLES is doing a good, though unostentatious, work. Thirty-one patients were enjoying its welcome succour at the beginning of the present year. The total expenditure during the twelvemonth had been £707 12*s.*, and £1200 had been added to the endowment fund, which now amounts to £12,000.

QUEEN'S UNIVERSITY IN IRELAND.—At a meeting of the Senate, held in Dublin Castle on Tuesday, the 30th ult., the following were elected examiners in the undermentioned subjects:—In Medicine: Professor O'Connor. In Surgery: William Thomson. In Midwifery: William K. McMordie. In Materia Medica: G. F. Duffey. In Medical Jurisprudence: M. O'Keefe.

ST. JOHN'S AMBULANCE ASSOCIATION.—It is reported that several new centres in connexion with this Association are in course of formation. Among the latest established, that of Dublin is likely to prove a great success. Altogether there are now seventy-seven centres in different parts of the United Kingdom, besides fifty-nine detached classes formed pending the institution of regular centres.

DEVONSHIRE HOSPITAL, BUXTON.—In recognition of Dr. Robertson's assiduous services to the institution, the committee of management of this hospital propose to complete the buildings of the hospital, now in course of extension, under the grant of £24,000 from the Governors of the Cotton Districts Convalescent Fund, by the erection of a portico and clock tower at the principal entrance, and an additional lodge, essential and integral parts of the plan of the architect, in accordance with the strongly and repeatedly-expressed wish of Dr. Robertson, consulting physician to the hospital, and chairman of the board of trustees and committee of management.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

ANDREWS, Mr. T. M., has been appointed Medical Officer for the Workhouse of the Pontardawe Union.

BENTLEY, C. E., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Kirton District of the Boston Union.

BLACKER, E. J. L., M.D., has been appointed Medical Officer to the B District of the Thrapstone Union, vice Bird.

BLOOD, Mr. F. W., has been appointed House-Surgeon to the Bucks Infirmary.

BROOKFIELD, J. S., B.A., M.D., has been appointed one of the Honorary Physicians to the Kilburn, Maida-vale, and St. John's-wood General Dispensary, vice Gawith, resigned.

COOPER, W., F.R.C.S.E., has been appointed Consulting Ophthalmic Surgeon to the Hospital for Epilepsy and Paralysis, Regent's-park, vice Wells, deceased.

DONOVAN, J., M.D., has been appointed Medical Officer to Skibbereen Dispensary and Workhouse, vice Donovan, deceased.

GEORGE, G. A., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Workhouse and the Dorchester District of the Dorchester Union, vice Emson, resigned.

HARGREAVES, M. K., M.B., C.M., has been appointed Resident Assistant Medical Officer to Shoreditch Infirmary, vice F. H. Walmsley, M.D.

LUNDY, L. F., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Sunbury District of the Staines Union.

MACGREGOR, P., L.R.C.P.Ed., has been appointed Medical Officer to the Crossland Moor Workhouse, Huddersfield Union, vice Rhodes, resigned.

MCLINTOCK, J., M.B., C.M., has been appointed Medical Officer for the two Marsden Townships of the Huddersfield Union, vice Hesslegrave, deceased.

MURRAY, Mr. H., has been appointed House-Surgeon to the Royal Westminster Ophthalmic Hospital, vice Martin, whose term of office has expired.

STURGE, A., M.D., has been appointed Physician to the Hospital for Epilepsy and Paralysis, Regent's-park, vice Clarke, deceased.

TAYLOR, M., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Workhouse of the Cannock Union, vice Blackford, resigned.

TITLEY, J., M.D., L.R.C.S.Ed., has been appointed Medical Officer for the Broughton District of the Glanford Brigg Union.

WALMSLEY, F. H., M.D., has been appointed Resident Assistant to Leavesden Asylum.

Births, Marriages, and Deaths.

BIRTHS.

BAKER.—On the 19th ult., at The Cedars, Tenterden, Kent, the wife of Charles Eaton Baker, M.R.C.S.E. &c., of a son.

DEANE.—On the 23rd ult., at 42, Albion-road, Stoke Newington, N., the wife of John Deane, M.R.C.S.E., L.R.C.P.Ed., of a son.

DICKSON.—On the 20th ult., at 33, Albany-street, Edinburgh, the wife of Frank K. Dickson, F.R.C.P.E., of Wye House, Buxton, of a son (Francis Henry).

LYLE.—On the 23rd ult., at Westbourne-square, Bayswater, the wife of William Vacy Lyle, M.D., of a daughter.

PILGRIM.—On the 20th ult., at Bridge-road, Leighton Buzzard, the wife of Forster John Pilgrim, of a son, which survived its birth but a few hours.

SALT.—On the 26th ult., at Egremont, Bournemouth, the wife of Henry Salt, M.D., of a daughter.

WALKER.—On the 28th ult., the wife of Arthur de Noé Walker, M.D., of a son.

MARRIAGES.

HODSON—WIENHOLT.—On the 30th ult., at St. Paul's, Herne-hill, Henry Algernon Hodson, M.R.C.S.E., L.R.C.P., of Bovey Tracey, South Devon, to Sarah Wormald, only child of William Wienholt, Esq., J.P., of Llanwern, Monmouthshire.

MARRIAN—WATKINS.—On the 17th ult., at the Parish Church, Wellington, by the Vicar (the Rev. Thomas Shepherd), James R. Marrian, L.R.C.P.Ed., of Birmingham, to Eliza, elder daughter of the late Richard Watkins, Esq., of Adzor House, Wellington, in the County of Hereford.

VIVIAN—SUGDEN.—On the 31st ult., at St. Paul's, Winchmore-hill, by the Rev. A. C. A. Drought, M.A., Vicar, assisted by the Rev. James Baird, M.A., Vicar of Southgate, R. T. Vivian, Surgeon, of Chase Side, Southgate, to Annie, daughter of Samuel Sugden, Esq., of Oak Lodge, Southgate, N.

DEATHS.

ADAMS.—On the 30th ult., at Eastham-street, Bungay, Suffolk, from acute pneumonia, Edward Burman Adams, M.R.C.S.E., L.S.A.L., aged 54.

BARLOW.—On the 18th ult., at Norfolk House, Albion-road, Dalston, Matilda Mary Ann (Mary), wife of Robert Barlow, M.R.C.S.E. Friends will kindly accept this intimation. Colonial papers, please copy.

CORBETT.—On the 25th ult., at the Garrison Hospital, Haslar, Brigade-Surgeon A. P. M. Corbett, M.D., aged 49.

HEATON.—On the 25th ult., at Stockwell House, Leek, Charles Heaton, M.D., in his 64th year.

KINGSTON.—On the 27th ult., at his residence, Sunnylands, Bath, Strickland Kearney Kingston, M.D., in his 78th year.

NASH.—On the 24th ult., at his residence, Pulteney-street, Bath, Joseph Nash, M.D., also of Brockley Hall, near Bristol, and Major 1st Somerset Volunteer Engineers, aged 58.

PILGRIM.—On the 24th ult., Charlotte Madeline (Lottie), the beloved wife of Forster J. Pilgrim, and daughter of the late G. S. D. Harris, Surgeons, both of Leighton Buzzard.

ROBINSON.—On the 28th ult., of typhus fever, after a short illness, Samuel Robinson, M.R.C.S.E., of Skibbereen.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"HOW A FLOWER MISSION WAS STARTED IN BIRMINGHAM."

THE above is the title of a small pamphlet published by Caswell, 200, Broad-street, Birmingham, giving particulars of the Flower Mission established in that town by the benevolent lady who writes under the initials H. R. During a six months' visit to America she saw the working of a Flower Mission in Chicago, and on taking up her residence in Birmingham began, in a small way at first, to imitate her American sisters. The work soon became known and talked of, and she was then able to proceed on a larger scale. A room in a central music warehouse was kindly placed at her disposal by the proprietors, and here the kind foundress and her band of willing workers meet every Friday. The first day, May 9th, 1879, seven ladies met, and, with the flowers kindly given by friends, made up forty-two bouquets, each with a card attached, on which a text was clearly written, and these were at once distributed to the different hospitals. More and more interest was taken in the benevolent scheme, and an ambulance of flowers has each week been sent. There is no lack of helpers, and on December 24th, the last day of meeting for the year, thirteen ladies made up 853 little bouquets, each with a Christmas card attached, which were distributed to six hospitals, five almshouses, three workhouses, two missions, and to the sick poor in twelve parishes. Nobody who has been in the habit of visiting invalids can have failed to see how much pleasure a few flowers give; and when we find that in the nine months the Flower Mission has been at work in Birmingham no less than 10,796 bouquets have been distributed, we can form some idea of the good work being done, and of the brightness that has been carried to hundreds of bedsides. So many people living in the suburbs of our large towns have flowers to spare for many months in the year, and the trouble of leaving or sending them to some central place once a week is so little, that we cannot but think the example of the ladies of Birmingham will be followed in other towns.

Mr. W. Freeborn.—We can only refer to our advertising columns.

FACTORY SURGEONCIES.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me if I have any right of appeal under the following circumstances? About a month ago the factory surgeonship for the township in which I reside became vacant. I made application for the office, but was passed over in favour of a practitioner residing in a neighbouring village, two and a half miles distant, and possessing the single qualification, L.S.A. I may mention that I have been practising for rather more than a year, and am the only registered practitioner in the village.

Yours &c.,

March, 1880. J. M.

MEDICAL CO-OPERATION IN THE UNITED STATES.

A MOVEMENT has been set on foot in San Francisco for the establishment of co-operative dispensaries, owned and supervised by prominent physicians. A number of these gentlemen, say ten or twelve, whose "offices" are in the same neighbourhood, associate for the purchase of a stock of drugs, rent a room, and employ a competent pharmacist, whose duty consists in simply making up their prescriptions. "The advantages to the physician of thus dispensing his own medicines," says the *Western Lancet*, "is unquestionable."

M.D.—Sir Trevor Lawrence, Bart., one of the Conservative candidates for Mid-Sussex, is the only son of the late Sir William Lawrence, under whom he received his professional studies at St. Bartholomew's Hospital, and was admitted a member of the Royal College of Surgeons in 1853.

Dr. A. Sheen.—We have no recollection of the paper.

"SHEEP ROT."

To the Editor of THE LANCET.

SIR,—Allow me space for a few remarks in reference to your annotation on "Sheep Rot" in your issue of March 13th.

You say "that 'rot' is in reality due to the presence in the liver and hepatic canals of numbers of Distoma." I have never seen "flukes" in the liver—i.e., in its structure; neither have I seen any sign of their having been located there. I have only seen them in the bile-ducts, which are undoubtedly their natural habitat, and to which they, doubtless, gain access by means of the common biliary duct. At least this would seem to be a more natural mode of access than by burrowing, as it is sometimes asserted they do, through the coats of the stomach, or by passing through the circulation to the liver. You also observe "that the parenchyma of the liver becomes atrophied from the compression the 'flukes' exercise upon it." Now, if this were the case, we should expect to find the amount of parenchymal disease bearing some proportion to the number of "flukes" in the biliary ducts; but this, practically, is not by any means a universal fact—frequently quite the contrary. There can, I think, be little doubt that the embryonic flukes find their way to the extreme peripheries of the ducts, and during their subsequent development set up a large amount of irritation and inflammation of the parietes of the canals and of the contiguous liver structure, which quickly leads to blocking up of the minute biliary outlets, and thus prevents the flow of bile into its natural channel, hyperæmia of the greater part of the liver being established, followed primarily by hypertrophy, and secondarily by atrophy and cirrhosis. In this form of verminous hepatitis, another result of inflammation—viz., fatty degeneration—is often seen.

Lastly, as reference has been made in several publications to the existence of "fluke disease" in the horse, I may observe that it has not been my lot as yet to discover a single specimen of Distoma in the liver of that animal, though I am quite prepared to admit that in colts feeding on contaminated pastures there is no physiological or other reason why they should not become infected; but I rather fancy the difference in the structure of the stomach of the horse as compared with that of ruminants would make it less favourable to the lodgment and further development of the "flukes." Cattle, both foreign and native, are frequently the subjects of "fluke disease"; but the influence it exerts upon them is far less deleterious than in the case of the sheep, owing to their greater constitutional strength, and to the fact that the entozoa are usually fewer in number, and a large extent of chronic liver disease may exist in the ox—as seen in hydatid disease and tubercle—without materially influencing the nutrition of the animal's body.

Your obedient servant,

THOMAS WALLEY,

March, 1880. Principal, Royal Veterinary College, Edinburgh.

Juvenis.—1. Yes, with moderate care and prudence.—2. Lodging money and servant's allowance, estimated at about £60 per annum.—3. Probably about £60.—4. No. The money allowance is the same. Quarters, when provided, are given according to rank.

Mr. Jas. Maitland.—We know nothing of the medicine named.

THE OPERATION OF TURNING IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—I believe that many young and inexperienced obstetric practitioners, as well as not a few old and experienced ones, are deterred from attempting the operation of turning with only one or two fingers in the uterus by the impression that the procedure is difficult and success unattainable, save by an expert such as Dr. Barnes or Dr. Braxton Hicks. Such an impression is erroneous, and probably tends to the loss of many lives. In my last five cases of turning I have successfully adopted the method referred to. In four of the cases there was not the slightest difficulty, and even external manipulative aid was unnecessary. In the fifth case contraction of the uterus and escape of the liquor amnii necessitated a little patience and also assistance from without, as directed by Dr. Barnes. The advantages of this method of turning are well known. Above all, risk to the mother—the most important of obstetric considerations—seems reduced to nothing, and the numerous cases in which turning is desirable before the os uteri will admit the operator's hand are successfully met.

I am, Sir, yours &c.,

Shipley, Yorkshire, March, 1880. W. J. SMYTH, M.D.

A FOREIGN BODY IN THE EYE FOR TWENTY-THREE YEARS.

DR. J. S. CHISOLM, of Baltimore, publishes, in the *Boston Medical and Surgical Journal*, a case in which a fragment of metal remained in the eye for twenty-three years without producing sympathetic ophthalmia. The patient, when a lad of sixteen, sustained the injury by the explosion of a gun-cap, a part of which struck him on the eye, cutting the cornea, and causing iride-cyclitis, through which inflammation the eyesight was lost. The irritation, however, subsided, and the organ, retaining almost its normal appearance, remained in a passive state till the man attained the age of thirty-nine, when he presented himself for treatment. The eyeball was then partially atrophic, somewhat corrugated, the cornea smaller than natural, but clear, and surrounded by a zone of ciliary injection, with some large sub-conjunctival vessels advancing from the back of the eye to the corneal border. The pupil was closed by old deposit, and upon the iritic surface near the centre was a yellowish-white spot about two lines in diameter. The organ was painful and very sensitive to the touch. The left and sound eye gave evidence of irritation. Extirpation was performed under chloroform. On examining the iris, especially with reference to the glistening spot upon its anterior face, a fragment of the cap was found imbedded in lymph.

Staff Surgeon.—Lieut. Charles Fergusson, who has just arrived in London with the loss of an eye, is the youngest son of the late Sir William Fergusson. The ball entered between his eyebrows, wounding the nose, and completely destroying the right eye.

TREATMENT OF PUERPERAL CONVULSIONS.

To the Editor of THE LANCET.

SIR,—I read the case of puerperal convulsions during labour, under the care of Dr. King, in last week's LANCET with much interest, especially as I had a somewhat similar case a few days since, and which unfortunately ended fatally.

In my case the convulsions set in two hours after labour. The person in question was a young woman, aged twenty-two years, the wife of a labourer, and her first confinement. The labour lasted about ten hours without any untoward symptom whatever, and the placenta came away in ten minutes after the birth of the child easily, and without any loss to notify. I left the woman doing well, cheerful, and with every prospect of continuing so. However, in about two hours, quite unexpectedly, convulsions having commenced, I was speedily sent for, and finding the pulse hard and full, face congested, and accompanying stertorous breathing, with partially dilated pupils, I immediately bled her, and ordered mustard poultices to the neck, calves of the legs, and cold applications to the head. This so far succeeded as to arrest the attacks for three hours, when they set in again. I had recourse to a further abstraction of blood, and gave her ten grains of calomel and one drop of croton oil, which relieved the bowels well twice. Notwithstanding the remedies, I regret to say the woman died in about twelve hours from the beginning of the attacks. I must add that she was of a plethoric habit, short-necked, stout, &c.

My chief reason for troubling you with a recital of this case is to bring before the profession for their opinion the following question:—Whether an hypodermic injection of morphia and atropia would have been appropriate treatment? having found such most effectual in arresting the most violent epileptic convulsions, the patients, in fact, being so violent as to require four persons to hold them down previous to inserting the injection; then the convulsions ceased immediately, and sleep for a few hours quite restored and refreshed the sufferer. Would it be prudent to adopt the same treatment in puerperal convulsions?

Yours truly,

Sarratt, Watford, March 29th, 1880. J. WRIXON, M.R.C.S.E., &c.

To the Editor of THE LANCET.

SIR,—In reference to the letter of Dr. King, on the subject of Puerperal Convulsions, which appeared in your last issue, I beg to instance a case lately under my care, in which a different treatment was tried.

The subject was a young woman, in fair health, pregnant with her first child, and three weeks short of her full time. I was called at 3 A.M., and found her in a state of eclampsia; her face livid, and frightfully distorted; pupils dilated; breathing loud and stertorous; the convulsions strong, unintermittent, and uniformly from the right to left side. On examination I discovered the os undilated. As the patient was totally unable to swallow, I ordered sinapisms to the calves and cold applications to the head, with the only result of slight mitigation of the symptoms. Calomel was tried on the tongue, but no deglutition was possible. The convulsions continued through the day, recurring about every quarter of an hour. In the afternoon I applied three or four leeches to the right temple, and, as the friends objected to chloroform, I prescribed an injection of chloral hydrate, forty grains, which was administered in the evening. A complete cessation of the convulsions ensued and a tranquil calm. Labour now set in, the os becoming normally dilated, and at 5 A.M. she was naturally delivered of a dead child. Unconsciousness continued for two days. I administered bromide of potassium in fifteen to twenty grain doses thrice daily for a few days, subsequently tonics. She made a good recovery. I might add that her father is a confirmed epileptic.

I am, Sir, yours obediently,

St. Faiths, Norwich, March, 1880. J. HAWKES, M.D.

THE DARMSTADT ALICE HOSPITAL.

THE *Quiver* for April contains the following brief account of this institution:—

"In an out-of-the way corner of the town, seldom or never visited by an ordinary tourist, stands a house in the Mauer Strasse which will ever be associated with the loved memory of the Princess Alice. Hither the Princess would come herself, unattended, constantly to see how the work of the place was going on, and to speak words of encouragement to the nurses, and read the word of Eternal Life to the poor and weary sufferers. The history of this institution is brief and simple. The late Princess Alice, Grand Duchess of Hesse, founded an institution named the Alice Frauen-Verein, or, as we should call it in English, the Ladies' Society. It embraces a school for training girls in industrial pursuits, an institution for orphans, and this hospital and school for training nurses. When the lamented Grand Duchess determined, in 1867, to organise a school for training nurses, there existed in the Mauer Strasse an old house, which had for some years been used as a small private hospital by some rising young physicians, who were anxious to have a place where they could themselves treat any poor cases which otherwise should have gone to the town hospital, and so passed out of their hands. These gentlemen made over the hospital to the Alice Frauen-Verein in 1867, after the war between Prussia and South Germany. In 1870, when the funds subscribed in England for the relief of the sufferers in the Franco-German war had been disbursed, there remained a considerable balance, and, through the influence of the Grand Duchess, it was arranged to devote this balance to building an addition to the old house, where the Training School for Nurses could exist in connexion with the hospital."

Mr. G. H. Macnamara.—Our abstract in English of M. Richet's paper was made from the original French. There is no English translation so far as we are aware.

An Intending Candidate should make application to the Secretary of the Brussels Medical Graduates' Association, Dr. Pocock, 20, Golborne-road, Upper Westbourne-park, W.

THE TREATMENT OF LATERAL CURVATURE OF THE SPINE BY ELONGATION.

To the Editor of THE LANCET.

SIR,—On reading the essay[1] on which I subjoin a few notes, I was much struck with the coincidence between the views expressed and those of Dr. Sayre. Mr. Stafford not only recognises the rotary displacement of the vertebræ, but figures a machine for the treatment of the patient by suspension. In the preface he says that the essays are part of the Jacksonian Prize of the Royal College of Surgeons, and adds: "In lateral curvature I flatter myself I have simplified and offered an original method of treatment—a method which at once takes these cases out of the hands of the charlatan and pretender, and places them in the power of the profession at large. I have only to add that my experience has proved the utility of the plan adopted."

In the essay (No. 2) he attributes lateral curvature to the inability of the spinal column to support the weight of the head and trunk. He recognises primary and secondary curves and their relation to the maintenance of gravity, and states that the primary curve is usually lumbar, but occasionally dorsal. He remarks that the cause of weak spine is deficient spinal muscle, which he attributes to the use of artificial support, and advises that girls be left without stays till they arrive at the age of fourteen or fifteen, so that all the muscles of the frame should be allowed their freest play. He calls attention to the shortening of the trunk and rotary displacement of the individual vertebræ: "In very bad cases of lateral curvature the bodies of the vertebræ are so thrown out of their situations that they are, as it were, rotated on the intervertebral substances, and instead of their anterior surfaces looking forward, they are turned laterally." After referring to the usual gymnastic exercises, and particularly exercise of the weak side, he describes and figures a machine, which he terms the "lateral rocker," which he says should be employed at least three times a day for a quarter or half an hour at a time. He details five cases of success with this machine. In addition to this, he says: "Lateral exercise, however, will not always recover a lateral curvature....More must be done. The spine itself must be elongated, and the best method of accomplishing this is by gravitation of the body. To effect this object I have invented a machine, by which the patient can be raised up from the ground by the upper part of the body, while the lower part hangs suspended." This he calls his "spine elongator." The machine consists not only of axillary supports, but of head and chin supports; in fact, his "spine elongator" is in every respect similar to Sayre's, excepting its tripod form. He only details two cases of its use, but says: "Several other cases of the same description, which it would be tedious to relate, and only repeating the same facts, I have treated in the same manner, and with equal success." It appears to me that these essays are well worthy of a more general recognition.

I am, Sir, yours &c.,

Guernsey, March 20th, 1880. JOHN AIKMAN.

[1] Two Essays on Diseases of the Spine. (1) On Angular Curvature of the Spine and its Treatment. (2) On the Treatment of Lateral Curvature by Gravitation, Lateral Exercise, &c. By R. A. Stafford, F.R.C.S. Eng., Surgeon Extraordinary to H.R.H. the Duke of Cambridge, &c. London: Longmans. 1844.

THE LATE DR. FAIRBANK.

IT should have been mentioned in our obituary notice of the late Dr. Fairbank (see THE LANCET, March 6th) that Dr. Ellison, who was in partnership with Dr. Fairbank, was appointed, jointly with the latter gentleman, as surgeon to Her Majesty's Household.

J. W. R.—1. Ranald Martin, or J. A. B. Horton on Tropical Diseases.—2. Sir J. Fayrer on the Relation of Filaria to Endemic Disease in India (THE LANCET, Feb. 8th and 15th, 1879).

A CASE ILLUSTRATING THE PATHOLOGY OF HERPES ZOSTER.

To the Editor of THE LANCET.

SIR,—The view usually held as to the pathology of zona is, as is well known, that the eruption is due to some irritation propagated along the course of the sensory nerves supplying the skin, and originating, according to von Barensprung, in the ganglia in the posterior roots of the spinal nerves. Trousseau, following Bazin, describes (very meagrely) a form of the affection, to which he gives the name of "arthritic zona," and which he considers to be rheumatic in its origin, and Hebra appears to hold a similar view. In the following case no history of rheumatism could be elicited, nor was the joint effusion which accompanied the eruption (and indeed preceded it) arthritic in regard to the symptoms which accompanied it, consisting as they did in mere pain and effusion, without diffused redness or heat or tenderness.

K. B——, a healthy-looking girl, aged twelve, presented herself for treatment, suffering from pain in the knee-joint (right). On examining the joint it was found to be swollen, and the patella "rode" freely, whilst there was a small patch of redness over the inner border of the patella. As already mentioned, there was no tenderness, nor was the joint hotter than the other; but, as there was no ground for adopting any other theory than that of a rheumatic cause, the joint was painted with iodine, and iodide and bicarbonate of potass administered internally. When seen the next morning, the patch of redness was found to have developed all the characters of herpes, and similar patches showed themselves all down the thigh in the course of the ilio-inguinal and anterior crural nerves. The knee was less painful, but otherwise there was no change in its condition. Next day the course of the long saphenous nerve, down to the heel, was involved in the eruption, and the fluid in the joint had diminished in amount. The treatment had previously been changed to the local application of collodion, and quinine and iron internally. On the fourth day the joint had regained its normal condition, and the eruption got rapidly well from that time. All possible care was taken to find out the causes which might have produced the effusion into the joint; but the only one which had facts in its favour was that the same irritation which had caused the eruption in the course of all the cutaneous branches of the anterior crural trunk (and must therefore have been considerable in amount) had been able, by its propagation along the branches of the same trunk (the nerves to the vasti internus et externus) which help to supply the knee-joint, to produce an analogous effect on the synovial membrane of that joint, and cause an effusion of fluid, accompanied by a very small amount of inflammatory action, and followed by rapid absorption. Such a condition in herpes zoster is sufficiently unusual to have remained unmentioned, though probably not unnoticed, hitherto; and the whole case may help to throw a light on the somewhat obscure operation of nervous irritation in producing the disorder in question.

Yours &c.,
EDWARD C. BOUSFIELD, L.R.C.P. Lond., &c.

Wandsworth, March 23rd, 1880.

Mr. H. Butler.—The portrait of Mr. Luther Holden, President of the Royal College of Surgeons, which has just been painted by Mr. J. E. Millais, will be exhibited this year in the Royal Academy. The portrait of Sir Wm. Fergusson was presented to the College.

VOTING PAPERS FOR UNIVERSITIES.

To the Editor of THE LANCET.

SIR,—I think attention should be drawn to the wording of the voting-paper for the Universities. In it the magistrate has to certify that the voter signs the paper in his presence and "*is personally known to him.*" It is this clause which I have italicized that I complain of. To-day I visited a resident magistrate for the purpose of swearing in my vote, but he refused to administer an oath to me or certify my signature on the ground that I was not "*personally known*" to him; and as I was not "*personally known*" to any magistrate in London I was prohibited from voting, and had to return the paper as useless.

I see by a morning paper that several persons met with a similar fate to mine at Hammersmith Police Court, and I was informed that others had been so treated at the police-station, Marlborough Street, where I attended.

I would recommend the re-wording of this clause in the voting-paper, for by its operation numbers must have been prevented from using their privilege at the recent elections.

I remain, your obedient servant,
R. VACY ASH, M.B. Aberd.

Naval and Military Club, Piccadilly, W., March 31st, 1880.

*** Instead of returning voting-papers as useless (!), graduates should apply at the offices of the local committee of the candidate they desire to support.—ED. L.

Junius.—It is a "standing order" of the General Medical Council that "the Registrar shall every year, within one month after the meeting of the Council, send to the various Bodies the names of those who have been struck off the Register." On referring to the last published list, the name of the person mentioned does not appear in that list.

Sarsiensis.—The article on the subject in "Cassell's Household Guide" is as good as any we are acquainted with.

"CARBOLIC ACID IN TYPHOID FEVER."

To the Editor of THE LANCET.

SIR,—In your number of Feb. 28th there is a case reported under the above heading, the result of which is quite at variance with my own experience.

In the early part of 1872 I treated almost simultaneously four cases of typhoid fever with carbolic acid internally, and regret to say that, as I had anticipated, the duration of the disease was not shortened at all. Since that date I have never had a case of typhoid in which I have not used carbolic acid internally, not, however, with the hope of limiting the duration of the fever, but to arrest decomposition of food.

While on the subject, may I suggest the case quoted by Mr. Weekes to have been one of "febris nervosa" or "abortive typhoid," the identity of which with typhoid I most positively deny; for the more I see of typhoid the more I am certain that, whether it runs a severe or light course, treatment will not shorten the period or render the disease abortive.

Faithfully yours,
Staunton-on-Wye, Hereford, March, 1880. PETER GILES, Jun.

A Fellow.—The statement in the Calendar of the College of Surgeons that the annual elections into the Council, and of President and Vice-Presidents, take place on a *Friday*, is evidently an error. These elections are held on the first and second *Thursday* in July respectively.

Delta should make application to Professor Liveing, Cambridge.

ELECTIONS AT THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—May I ask you to insert in your next issue the following statement of facts?

Mr. T. H. Bartleet, a well-known Birmingham surgeon, who has taught Anatomy and Physiology in our school for eighteen years, was nominated, for the recently vacant office of Examiner in Physiology at the Royal College of Surgeons, by Mr. Henry Power, who had special knowledge of Mr. Bartleet's capabilities for the post, and whose judgment on such a matter is, I presume, above cavil. Mr. Bartleet had been nominated on at least one previous occasion. He was prepared to fulfil the duties of the office at any sacrifice. On Thursday last the Council accepted the recommendation of the Examination Committee, and elected Mr. Jeremiah M'Carthy, of St. Mary's Hospital. Mr. M'Carthy is two years Mr. Bartleet's junior as a Fellow, and six years his junior as a Member of the College. There is not, I believe, a single provincial surgeon or representative of a provincial medical school on the Board of Examiners.

Yours faithfully,
Birmingham, March 15th, 1880. JOHN ARCHER, F.R.C.S.

MEDICAL CHARGES.

To the Editor of THE LANCET.

SIR,—As a general practitioner, my account for the attendance, as detailed by "Extra-urban Practitioner," would have been five guineas. I always charge a double fee for the first visit, as it is then time has to be spent in diagnosis, giving directions, &c. I also charge extra (generally double) in special visits, and never less than a guinea for consultation. I also charge double visiting fees in contagious cases. My experience is that half a guinea is just as cheerfully paid for a visit as 7*s.* 6*d.*; but (and I think this very important) my patients know that I never pay them an unnecessary visit.—Yours obediently,

ONE WHO WOULD ENTREAT THE PROFESSION
March 30th, 1880. TO RAISE THE STANDARD OF FEES.

Medical Student.—The Registrar of the General Medical Council, 315, Oxford-street, will give all information on the subject.

Dr. Edwin Dobson. — 1. Austin Flint, Williams, Douglas Powell.—2. Dickinson.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—Would you oblige me by allowing me to state that, owing to similarity of names, a misunderstanding has arisen in some quarters that I have resigned my appointment as one of the physicians of King's College Hospital; whereas, as you are aware, it is my colleague, Professor Gerald Yeo, who has resigned the office of assistant-surgeon.

Yours truly,
Hertford-street, Mayfair, March 27th, 1880. I. BURNEY YEO.

HORSE FURNITURE, ARMY MEDICAL DEPARTMENT.

To the Editor of THE LANCET,

SIR,—I take advantage of your pages to draw attention to the very ugly horse furniture laid down for A.M.D. officers. The following changes are needed:—Bosses on the bit, bearskin wallet-covers, and departmental gold-lace on saddle-cloth. Nothing can be uglier than the present trappings; they are utterly funereal.—Yours, &c.,

March, 1880. I. V. R. C.

THE

Lumleian Lectures

ON

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.

Delivered before the Royal College of Physicians,

BY WM. ROBERTS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL MEDICINE TO THE OWENS COLLEGE.

LECTURE I.—PART II.

DIASTATIC FERMENTS—DIGESTION OF STARCH.

THE importance of starch as an article of human food has, perhaps, scarcely been duly recognised. If we regard the enormous proportion in which the seeds of cereals and leguminous plants and the tuber of the potato enter into our dietary, and the immense percentage of starch in these articles, it is probably not too much to say that fully two-thirds of the food of mankind consists of starch.

In the raw state, starch is to man an almost indigestible substance; but when previously subjected to the operation of cooking it is digested with great facility.

Diastase has only a feeble action on the unbroken starch granule, even at the temperature of the body. In the lower animals, and in germinating seeds, the starch granule is probably attacked in the first instance by some other solvent, which penetrates its outer membranes, and thus enables the diastase to reach and act on the starchy matter contained within. By the aid of heat and moisture in the process of cooking, the starch granule is much more effectively broken up. Its contents swell out enormously by imbibition of water, and the whole is converted, more or less completely, into a paste, or jelly, or mucilaginous gruel. It is in this gelatinous form exclusively, or almost exclusively, that starch is presented for digestion to man.

The digestion of starch is accomplished by the saliva and pancreatic juice, both of which are rich in diastase. Diastase also exists abundantly in the liver, and in smaller quantities in the intestinal juice, in the blood, the urine, and apparently in all the interstitial juices. Diastase from all these diverse sources appears to act substantially in the same manner on starch, changing it by a progressive hydrolysis into sugar and dextrine.

If the action of a fluid containing diastase—say saliva or extract of pancreas—on starch paste be watched, the first effect observed is the liquefaction of the paste and the production of a diffluent solution. This change is effected with great celerity—in two or three minutes the stiff paste becomes a watery liquid. This is evidently a distinct act—and antecedent to the saccharifying process which follows. By operating with small proportions of diastase and large proportions of pure starch paste it is possible to hit on a moment when liquefaction is complete and saccharification is not yet begun. At this moment the solution yields a pure starch reaction, and no reaction of dextrine nor of sugar. The process of saccharification follows immediately on the heels of liquefaction; and in ordinary manipulations the one process runs into the other.

The speed of the action depends primarily on the proportion of the diastase. By adjusting the proportions of diastase and starch in such degrees that saccharification will be completed in about a couple of hours, the successive steps of the process can be leisurely followed by applying from time to time the appropriate tests.

If you test as soon as liquefaction is complete you get a pure blue with iodine and a slight reaction of sugar with Fehling's solution. In a few minutes the sugar reacti n becomes more decided; and, although you still get a pure blue with iodine in the ordinary way of testing, you will get, by greatly diluting the blue solution and then adding more iodine, a deep violet tint—showing the presence of erythro-dextrine mixed with starch. The next step is the total disappearance of the blue reaction with iodine, and the substitution for it of an intense reddish-brown colouration of erythro-dextrine. By and by the reddish-brown colour is replaced by a yellowish-brown—indicating the preponderating presence of a different kind of erythro-dextrine. Meanwhile the sugar reaction goes on increasing. The next step is the entire disappearance of any kind of colouration with iodine. But the action is still very far from complete—the proportion of sugar goes on increasing for a considerable time after iodine has ceased to tint the solution. At length however matters come to a standstill, and the proportion of sugar ceases to increase.

The explanation of this series of reactions is impossible on the old view of the constitution of starch. Until recently it was supposed that the starch molecule was represented by the comparatively simple formula $C_{12}H_{20}O_{10}$, and that under the influence of diastase this molecule was resolved by hydration into two molecules, one of dextrine and one of grape-sugar.

The researches of Musculus and O'Sullivan[1] have shown that this is not a correct account of the transformation. In the first place it was found that the sugar produced was not grape-sugar (dextrose), but another kind of sugar called *maltose*. It was also found that the dextrines first produced, and which were coloured red or brown by iodine, were progressively changed, with simultaneous production of sugar, into a series of dextrines of a lower type which did not yield any colouration with iodine. To these latter kinds of dextrine the term achroo-dextrines has been applied.

As maltose is now ascertained to be the kind of sugar which is mainly produced in the digestion of starch by diastase, this body assumes a new and considerable importance in physiological chemistry, and it will not be out of place here to give some description of its properties. Maltose is a fermentescible, crystalline sugar of the saccharose (cane-sugar) class, having very little sweetening power, and possessing one atom less water than grape-sugar. Its formula is $C_{12}H_{22}O_{11}$. It possesses more rotatory power on polarised light than grape-sugar, but has considerably less power of reducing cupric oxide. The rotatory power of maltose is +150, that of grape-sugar +58. The reducing power of maltose is 61 compared to that of grape-sugar as 100. Maltose can be hydrolysed into grape-sugar by prolonged boiling with dilute acids. Malt-diastase does not possess this power, but we shall presently see that the diastatic ferments of the small intestine are able slowly to effect the same change.

The researches of Musculus and O'Sullivan have rendered it necessary to assume that the molecule of soluble or liquefied starch is a composite molecule, containing several members of the group $C_{12}H_{20}O_{10}$—which is to be regarded as the constituent radical of the composite starch molecule. The starch molecule must in the future be represented by the formula $n(C_{12}H_{20}O_{10})$—the value of n not being yet definitely agreed upon.

Two able chemists of Burton-on-Trent, H. T. Brown and J. Heron, have extended these researches, and fully confirmed the main conclusions of Musculus and O'Sullivan. In a recent publication (*Journ. Chem. Soc.*, Sept. 1879), they have for the first time presented a fairly complete scheme of the succession of changes undergone by starch under the action of diastase. These chemists assume that the molecule of soluble starch consists of ten members of the group $C_{12}H_{20}O_{10}$, and that its formula should be written $10(C_{12}H_{20}O_{10})$. This view greatly facilitates the comprehension of the progressive hydrolysis of starch by diastase.

We have seen that starch in the condition of paste or jelly is distinguished sharply by its physical properties from liquefied or soluble starch. There must therefore in all probability be some difference of molecular aggregation between starch in these two states—and it will not be a very bold assumption to suppose that starch in the gelatinous state consists of still more complex molecules than soluble starch—and that several molecules of soluble starch are grouped together to form the molecule of starch in the gelatinous state.

On the ground of these assumptions we may represent the successive steps of the digestion of gelatinous starch by the following series of equations.

The molecule of gelatinous starch $= n(C_{12}H_{20}O_{10})$ is first resolved into n molecules of soluble starch. The molecule

[1] O'Sullivan's papers are published in the Journal of the Chemical Society, from 1872 to 1876. A full account of these researches is given in a paper in the same journal for September, 1879, by T. H. Brown and J. Heron.

Digitized by Google

of soluble starch is then resolved by progressive deduplication and hydration into dextrine and maltose by the following succession of steps :—

One molecule of soluble starch $= 10(C_{12}H_{20}O_{10}) + 8(H_2O) =$

1. Erythro-dextrine α $9(C_{12}H_{20}O_{10}) + (C_{12}H_{22}O_{11})$ maltose.
2. Erythro-dextrine β $8(C_{12}H_{20}O_{10}) + 2(C_{12}H_{22}O_{11})$,,
3. Achroo-dextrine α $7(C_{12}H_{20}O_{10}) + 3(C_{12}H_{22}O_{11})$,,
4. Achroo-dextrine β $6(C_{12}H_{20}O_{10}) + 4(C_{12}H_{22}O_{11})$,,
5. Achroo-dextrine γ $5(C_{12}H_{20}O_{10}) + 5(C_{12}H_{22}O_{11})$,,
6. Achroo-dextrine δ $4(C_{12}H_{20}O_{10}) + 6(C_{12}H_{22}O_{11})$,,
7. Achroo-dextrine ϵ $3(C_{12}H_{20}O_{10}) + 7(C_{12}H_{22}O_{11})$,,
8. Achroo-dextrine θ $2(C_{12}H_{20}O_{10}) + 8(C_{12}H_{22}O_{11})$,,

The final result of the transformation is represented by the equation $10(C_{12}H_{20}O_{10}) + 8H_2O = 8(C_{12}H_{22}O_{11}) + 2(C_{12}H_{20}O_{10})$.
Soluble Starch. Water. Maltose. Achroo-dextrine.

We must conceive that the energy of the ferment is exercised in gradually pulling asunder the component groups or radicals of the unstable molecule of soluble starch, detaching one after another from the parent molecule, each radical as soon as detached assuming an atom of water and becoming an atom of maltose. At each detachment the parent molecule draws its remaining groups together to form a new kind of dextrine. As the process goes on the dextrine molecule becomes smaller and smaller—that is, contains fewer and fewer component radicals; the higher dextrines giving a red or brown colouration with iodine, but the lower dextrines giving no reaction with iodine.

It is to be noted that after the transformation has reached its final term there still remains a portion of achroo-dextrine unconverted into maltose. Upon this remnant diastase has only a very slow action. The percentage result, when the reaction is completed, gives, in round numbers, eighty parts of maltose and twenty parts of achroo-dextrine. The eight varieties of dextrine indicated in the above table of equations have not all been obtained in the separate state, but there is strong evidence of the existence of at least several of them as distinct bodies.

The account just given of the transformation of starch has been deduced from a study of the action of diastase derived from malt. The question arises—physiologically an important question—whether the action of salivary and pancreatic diastase is identical with that of malt-diastase. The researches of Musculus and V. Mering[2] give an affirmative answer to this question. These observers found that saliva and pancreatic extract act on starch paste in the same way as malt-diastase, the final products in all cases being achroo-dextrine and maltose, and not dextrose (grape-sugar). At my suggestion Mr. H. T. Brown was good enough to submit the question to a fresh examination in regard to pancreatic extract. His results fully confirm the conclusions of Musculus and V. Mering. He found, however, that there was a slight difference in the results when the action of pancreatic extract and malt-diastase on starch were continued a long time. The pancreatic ferment, in addition to the power, which it shares with malt-diastase, of slowly converting the lowest achroo-dextrine into maltose, exhibited a power of slowly changing maltose into dextrose (grape-sugar) which is not possessed in any degree by malt-diastase. Mr. Brown also informs me that there is in the small intestine a ferment which possesses similar properties.

The respective shares of Saliva and Pancreatic Juice in the Digestion of Starch.

The respective shares of saliva and pancreatic juice in the digestion of our farinaceous food is probably variable and perhaps not quite identical.

As all our farinaceous food is eaten after being cooked, the starch in it is more or less completely gelatinised; it is, therefore, probable that one of the chief uses of salivary diastase in man is to liquefy starch jelly. A very brief contact suffices for this, and it is manifest that the accomplishment of this change is an important advantage in the subsequent operations in the stomach. Our gruels, blancmanges, puddings, and similar farinaceous dishes owe their thick pasty condition to starch in the gelatinous state, and nothing can be imagined more resistent to the rapid permeation of the meal by the gastric juice, and to the pulping of it into a uniform chyme, than the presence of coherent masses of starch paste. If the saliva performed no other service than this it would furnish an important aid to digestion of a meal.

[2] Maly's Jahresbericht für Thier-Chemie for 1878, p. 40.

There has been considerable dispute as to whether, and how far, the saccharification of starch goes on in the stomach. My observations lead to the conclusion that this depends on the degree of acidity of the contents of the stomach, and it is known that this varies within very wide limits. When a meal is swallowed it takes some time for the gastric juice to permeate the mass, and the acidity of the gastric contents is for some time very feeble. As digestion proceeds the contents of the stomach tend to become more and more acid. This is a point which each one can observe for himself. The stomach is by no means reticent of its doings. The posseting which we see in infants goes on in a less degree in the adult, and we are perforce made aware, sometimes inconveniently so by our palates, of the ascending scale of acidity in the stomach. Saliva acts energetically in neutral and in slightly acid media, but its activity is checked and finally arrested when the acidity becomes pronounced. When digestion is proceeding comfortably and normally a certain interval elapses before the acidity of the stomach becomes considerable, and during this interval the salivary diatase continues active, and has time to accomplish a good deal of work. But we must remember that our farinaceous food is, for the most part, not in the most favourable condition for rapid digestion. It is not generally in a state of mucilage, but in the form of a solid paste, as in bread, puddings, and pastry. A good deal of it, too, is imperfectly cooked. Consequently, the larger part of our starchy food reaches the duodenum still unchanged, or only partially changed, and this larger part of the work is consummated by the pancreatic juice in the alkaline medium of the small intestine. I shall have to return to this point in speaking of gastric digestion.

It has been noted as curious that the saliva of man possesses more diastatic power than that of almost any other animal. Among the herbivora, which are such large consumers of starch, the saliva has comparatively little diastatic power; and in some, as in the horse, it is almost or altogether wanting. I apprehend that this is due to the fact that man alone has learnt to cook his starchy food, and that the diastatic power of his saliva has become developed with the opportunity for its exercise. Diastatic power would be thrown away in the saliva of the horse, because he eats his food in the raw or uncooked state, and saliva is without action on raw starch.

When can Starch be said to be fully Digested?

Seeing that in the digestion of starch a number of intermediate products are evolved, the question arises when can the digestion of starch be said to be accomplished? Is maltose the only product absorbed, or are not the dextrines, especially the achroo-dextrines, also absorbed? The dextrines, even those coloured by iodine, are highly diffusible, and pass freely through parchment paper in dialysis. In this respect they contrast strongly with starch jelly, and even with liquefied (or soluble) starch, both of which are undialysable. It seems not improbable that the lower dextrines are largely absorbed. Because if we follow the history of starch after it has been transformed by digestion, and absorbed, we are confronted with the remarkable fact that after absorption the products of starch digestion, or at least a large portion of them, undergo a reconversion in the liver into a substance closely resembling undigested starch. Glycogen, in its essential features, is an exact counterpart of soluble starch. It forms an opalescent solution in water; it is undialysable, and it is transformed by diastase into dextrine and maltose.

It appears reasonable to suppose that it would be an advantage to the economy if that portion of our starchy food which is destined to be stocked in the liver as glycogen should be absorbed at an early period of the digestion, because the less removed the digested product is from starch at the moment of absorption the fewer steps it will have to retrace in recovering the amylaceous state after absorption.

It is not necessary to suppose that the ascending steps of the reconversion are identical with the descending steps of digestion, but it is probable that they are fundamentally alike, seeing the close similarity of the products at the two ends of the journey. At any rate, there is no warrant in the present state of knowledge for the opinion that sugar is the only absorbable product of starch digestion.

Absolute Energy of Diastase.

The notion that the energy of diastase is not consumed in action seems, on *à priori* grounds, to be quite untenable; such a notion contravenes a general principle in physics,

Digitized by Google

that energy in performing work is expended and finally exhausted. It is easy to show experimentally that diastase is no exception to this rule. Payen and Persoz estimated that malt diastase was able to convert two thousand times its weight of starch into sugar. My own experiments with extract of pancreas indicated a much higher power than this. The following experiment illustrates at the same time the enormous diastatic power of pancreatic diastase and the fact that this power is strictly limited.

A quantity of starch mucilage was prepared, containing one per cent. of pure potato starch—100 cubic centimetres of this mucilage contained exactly one gramme of dry starch. The pancreatic extract employed was prepared in the following manner:—Fresh pig's pancreas, freed from fat, was rubbed up with an equal weight of fine sand until it became a smooth uniform pulp. This pulp was spread out very thinly on sheets of glass, and allowed to dry in the open air for a fortnight. It was then scraped off with a knife, and formed a rough shreddy sort of powder. 125 grammes of this mixture of pancreas and sand were infused, at the temperature of the room, in 1000 cubic centimetres of saturated chloroform water, with a little more chloroform added to insure against decomposition. The mixture was allowed to stand for four days with occasional agitation, and the product was then filtered clear through paper. The extract of pancreas thus prepared proved a very serviceable preparation, and most of my observations on pancreatic digestion were made with it.

This extract was found to be so extremely active that it was necessary to dilute it largely in order to bring the quantities of starch operated on within due compass. Accordingly a dilution was made of one cubic centimetre of the extract in 1000 cubic centimetres of water. Five numbered phials were then severally charged with 100 cubic centimetres of the prepared starch mucilage—so that each phial contained exactly one gramme of dry starch. One cubic centimetre of the diluted pancreatic extract was added to phial No. 1, two cubic centimetres to No. 2, four cubic centimetres to No. 3, six cubic centimetres to No. 4, and eight cubic centimetres of the same diluted extract to phial No. 5. The phials were then corked and placed in a warm chamber, where the temperature was steadily maintained by a Page's regulator at 100° F. (38° C.)

At the end of twenty hours the contents of the phials were examined. All of them were perfectly transparent, and had entirely lost the opalescent appearance of the original starch mucilage, and not a vestige of sediment existed in any of them. The following reactions indicated the progress of the transformation.

No. 1 gave an intense blue colouration with iodine, and when the blue solution was largely diluted and more iodine added, it developed a violet tint which showed the presence of erythro-dextrine; it also reduced the cupro-potassic solution freely.

No. 2 gave a strong blue reaction with iodine, and by diluting and adding more iodine, the colour changed to a deep claret-red, indicative of abundance of erythro-dextrine. This and all the rest gave a strong sugar reaction with Fehling's solution.

No. 3 yielded no blue reaction with iodine, but an intense port-wine colouration of erythro-dextrine.

No. 4 gave no blue reaction with iodine, and only the faintest possible brown colouration with that reagent, showing only traces of erythro-dextrine.

No. 5 exhibited not a vestige of reaction with iodine. It contained neither starch nor erythro-dextrine, but it yielded a strong sugar reaction.

The transformation of No. 5 might be regarded as complete, but the rest still contained starch or erythro-dextrine, or both. Nos. 1, 2, 3, and 4 were restored to the warm chamber and re-examined at the expiration of seven hours. No. 4 no longer gave the slightest reaction with iodine, but Nos. 1, 2, and 3 showed only slight signs of further alteration, and were returned to the warm chamber.

At the end of forty-eight hours from the commencement of the experiment, Nos. 1, 2, and 3 were examined again. No. 1 showed a strong blue colouration with iodine, and also a strong reaction of erythro-dextrine. No. 2 no longer gave any blue tint with iodine, but it exhibited an intense erythro-dextrine reaction. No. 3 only gave a yellowish-brown reaction with iodine of moderate intensity.

After a further sojourn in the warm chamber of seventy hours the contents of the three phials were not found to be sensibly altered; they gave exactly the same reactions as before. It was evident that in these phials the diastatic action had run its course to an end within the period of forty-eight hours, and that the solutions had then come to a state of rest, the ferment had liberated all its energy, the limits of its power had been reached, and the task allotted to it was left unfinished. Nevertheless it had accomplished an amount of work which, considering its infinitesimally minute mass, appears marvellous. We shall now endeavour to measure approximatively the amount of this work as indicated by the above experiments.

The original pancreatic extract, when evaporated to dryness in a water-bath, was found to leave a residue of 1·5 per cent. of organic matter. This organic matter included, besides diastase, a quantity of proteolytic ferment (trypsin) and a certain quantity of the milk-curdling ferment. It also included a certain quantity of digested proteid matter, for in making an extract of the pancreas there is always accomplished some self-digestion of the glandular tissue.

Taking into account these various admixtures, it would appear a very liberal allowance to estimate the diastatic ferment as amounting to one-fourth of the total organic matter. This would give us for the original extract a proportion of diastase in round numbers of 0·4 per cent., and for the diluted extract of 0·0004 per cent.

The proportion of diastase added to phial No. 4 seems to have hit off with precision the limit of quantity required to transform one gramme (15·5 grains) of starch in forty-eight hours at a temperature of 100° F. (38° C.) The amount of diluted extract added to this phial was six cubic centimetres, and on the basis of the above estimate, this represents a quantity of net diastase amounting to 0·000024 gramme. This yields us, by an easy calculation, the astounding result that pancreatic diastase is able to transform into sugar and dextrine no less than 40,000 times its own weight of starch!

The speed at which a given quantity of starch is transformed by diastase depends essentially on the proportion of ferment brought to act upon it. In the above experiments the proportion of diastase was very minute in comparison with the amount of starch, and the action went on slowly for forty-eight hours. But if we reverse these proportions and mix a small amount of starch with a large amount of diastase the transformation is instantaneously accomplished.

If a test-tube be half filled with an active extract of pancreas and a few drops of starch mucilage be quickly shaken therewith, you cannot detect the reaction of starch or dextrine in the mixture, however prompt you may be with the testing—the transformation has followed on the admixture as instantaneously as the explosion of the charge follows the fall of the trigger. Between these extremes there are all gradations. This mode of action differs entirely from what is seen in the operation of ordinary chemical affinity. If you add a drop of acid to an excess of alkali, the acid is instantly neutralized and the action comes to an end; and conversely, if you add a drop of alkali to an excess of acid, the action is equally instantaneous; the affinity of the two bodies for each other is a mutual affinity. But this is not the case with the action of diastase on starch. The starch appears entirely passive in the process; all the energy is on the side of the diastase, and this energy can only be liberated gradually. There is something in this strikingly suggestive or reminiscent of the action of living organisms. To illustrate my meaning, let us compare the particles of the ferment to a band of living workmen whose function is to scatter little heaps of stones. If the heaps are few and the workmen many, all the heaps will be scattered at once, and the energy of the workmen will still remain sensibly unimpaired. But if the heaps are millions and the workmen hundreds, and if the workmen are doomed to labour on until they fall exhausted at their task, the scattering of the heaps will go on for a comparatively long time, and the process of exhaustion will be a gradual one.

I may here mention that the diastatic ferment does not exist in the saliva and pancreatic juice of young suckling animals, except in minute proportions. Its quantity increases when the teeth are cut. In the human infant diastase does not appear to exist in sufficient abundance to digest starchy matters effectively until about the sixth or seventh month. Until this period it is therefore not advisable to administer farinaceous food to infants.

DIGESTION OF CANE-SUGAR—INVERSIVE FERMENT.

Bernard[3] first called attention to the fact, already mentioned, that cane-sugar (saccharose) required digestion both

[3] Claude Bernard, Leçons sur les Phénomènes de la Vie, tom. ii. p. 36. Paris, 1879.

Digitized by Google

in animals and plants before it could be utilized in nutrition. The cane-sugar stored up in beet-root and in the sugar-cane is changed by ferment-action into invert-sugar before it is permitted to circulate in the sap, and take part in the nutritive operations of the plant. He found also that an analogous transformation was requisite before cane-sugar could be assimilated by animals. He states that when cane-sugar is injected into the blood it circulates therein as an inert body, and is in no degree used as nutriment by the tissues, but is eventually entirely removed unchanged with the urine. Cane-sugar is, however, an important article of food, and is consumed by us in large quantities every day; and we know that when thus consumed it does not behave like an inert matter, circulating a while in the blood, and then being eliminated by the kidneys as a waste product. It is evidently absorbed and assimilated, and must, therefore, somewhere or other be transformed or digested in animals as it is in plants. Reasoning this way, Bernard sought for an inversive ferment for cane-sugar in the alimentary tract; and after searching in the saliva, in the stomach, and in the pancreas in vain, he at length discovered it in the small intestine. In the small intestine he found that cane-sugar was transformed into invert-sugar, and by a similar ferment with that destined for analogous purposes in yeast, in beet-root, and in the sugar-cane.

The transformation of cane-sugar into invert-sugar is represented by a very simple equation:—

$$\underset{\text{Saccharose.}}{2C_{12}H_{22}O_{11}} + \underset{\text{Water.}}{2H_2O} = \underset{\text{Dextrose.}}{C_{12}H_{24}O_{12}} + \underset{\text{Lævulose.}}{C_{12}H_{24}O_{12}}$$

The inversive ferment was detected by Bernard in the small intestine of dogs, rabbits, birds, and frogs. Balbiani found it in the intestine of the silk-worm. It was recognised by myself in an extract of the small intestine of the pig, the fowl, and the hare. It does not exist in the large intestine.

But, although my observations on this subject coincided in the main with those of Bernard, I noted two points which I think merit further attention. The first was that while a piece of small intestine infused in water yielded a mixture which was capable of inverting cane-sugar, the same infusion when filtered through paper until it was perfectly clear had no such power. It seemed as if the inversive ferment did not pass freely, if at all, into true solution, but remained attached to some of the formed elements contained in the intestine. The second point I noted was the extreme slowness of the action. When cane-sugar was added to the unfiltered infusion of intestine, and the mixture maintained at blood heat, it generally took a couple of hours before a reducing effect with the copper test could be obtained. Both these circumstances reminded one of the action of formed ferments, and I could not help thinking that there was here something which required clearing up at some future time.

THE

Gulstonian Lectures

ON

EPILEPSY.

Delivered before the Royal College of Physicians,

BY W. R. GOWERS, M.D., F.R.C.P.,

SENIOR ASSISTANT-PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE III.—PART III.

THE treatment of epilepsy is a subject on which numerical analysis gives little help. A large number of cases are under observation too short a time to enable the effect of remedies to be fairly estimated; and of the cases in which benefit is derived, we have no means of ascertaining how many relapse when treatment is discontinued. My notes of the result of treatment in this series of cases extend to 562 cases only. In the remainder, either the period of observation was too short for a just conclusion to be drawn, or, in the press of out-patient work, the influence of remedies was not noted with sufficient precision. The effect of treatment is more likely to be recorded when it is distinct and considerable than when it is slight. Hence the following figures have no relative value. Of the 562 cases, the attacks ceased while the treatment was maintained in 241; doubtless many of these relapsed when treatment was discontinued, but in a few I have been able to ascertain that the patients remained free from fits even for years after they ceased to take medicine. In 266 cases improvement short of arrest was obtained; the fits being reduced in many to $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, and even $\frac{1}{10}$ of their former frequency. In 55 cases little improvement was obtained by any method of treatment.

Time forbids me to enter at any length on the details of treatment, and I can do little more than mention the remedies which in this series of cases were of most distinct service. The subject of possible modes of action it is better to leave almost untouched. It may be doubted whether a rational therapeutics of epilepsy is yet possible. At any rate, up to the present time remedies used empirically have been of most service.

Although the results show that we must not only rely exclusively upon bromides in our treatment of epilepsy, they show also, as might be expected, that on these our chief trust must still be placed. Of the arrests of fits, 66 per cent., and of the improvements short of arrest, 62 per cent., were due to bromides given alone. Of the three alkaline salts of bromide, that of potassium deserves, I think, as it has popularly received, the first place. I have made a careful comparison between the salt of sodium and potassium in a series of about fifty cases, substituting the one for the other. In a few cases the sodic salt appeared to do better; in the great majority it was distinctly less useful. Bromide of ammonium possesses slightly more power than bromide of potassium, but this is not greater than the larger quantity of bromine which it contains will account for.

The period after its administration at which maximum effect of a dose of bromide is obtained varies, I believe, with the dose. The larger the dose the longer is maximum effect deferred; the smaller the dose the sooner does it occur, and the sooner is its action over. When small doses are employed in cases in which attacks occur at regular times, they should not therefore be given more than two or three hours before the attack is expected. This is contrary to some opinions which have been expressed, but I have several times known attacks arrested when a dose was given some two or three hours before the fit was expected, which were not arrested when the same dose was given twelve hours earlier.

The effect of bromide upon fits appears to be for a time cumulative, just as is, indeed, its action in causing bromism. Attacks may continue under its administration for a time, and yet ultimately cease without any increase in the dose. On the other hand, still later, tolerance, or rather indifference, may be established, and attacks which have been for a time arrested may ultimately recur.

Drugs which increase reflex action, such as strychnia, are now believed to do so by lessening the resistance in the nerve-centres involved. Bromide diminishes reflex action, antagonises strychnia, and it is probable that it does so by increasing the resistance in the centres. If the view above expressed be correct, that the morbid state in epilepsy is essentially an instability of the resistance in the cells, it is also probable that bromide acts by increasing the stability of this resistance.

Bromide is commonly administered in a continuous course, in such moderate doses as will just suffice to keep the fits in check. Given thus it needs to be given frequently. I have more than once observed that a daily quantity which given in two doses did not quite arrest the fits, arrested them completely when given in three doses. If, therefore, the greater convenience of infrequent doses, one or two daily, is preferred, a somewhat larger quantity needs to be given.

When bromide is thus given continuously, it has not seemed to me desirable to increase the daily dose beyond a drachm or a drachm and a half. If this does not arrest the fits, I have very rarely found that larger doses succeed so well as the combination of bromide with other drugs. But it is, I think, open to question whether this method of administration, using doses only just sufficient to arrest the fits, is the wisest in all cases. If bromide cures epilepsy, as without doubt it does sometimes, it must be by effecting a nutritive change in the nerve-cells corresponding to its action, whereby they are rendered permanently more stable. That it, or any other drug, does good in epilepsy by influencing the vascular state of the brain, appears to me without even probable proof. Even if such were its action, we are only driven back to a similar influence in increasing the

Digitized by Google

stability of the cells of the vaso-motor centre. There are, I think, many grounds for the belief that the change in the nutrition of the cells may be produced more effectually by subjecting the patient *for a time* to the full influence of bromide, giving doses much larger than are needed to arrest the fits, in the hope of producing more readily a permanent nutritive change. In giving bromide thus I have preferred large doses at intervals of two or three days, gradually increasing the dose until it is as large as can be well borne, and then diminishing it. The largest single doses which I have given in this way have been doses of one ounce. This in some patients produces slight stupor, sometimes reaching its maximum on the second day after the dose. In other cases it produces very little disturbance beyond headache. From the marked differences which patients present in their tolerance, it is not well to begin this method of treatment with a larger dose than four drachms.

The value of the various combinations of bromide with other drugs was tested, as far as possible, on a uniform plan. First, bromide was given alone for several months, and then additional drug was added to the same dose of bromide, and the result watched for several months longer. Of the various combinations which are in common use, those with digitalis and belladonna unquestionably deserve, as they have commonly received, the first place. Digitalis is one of the oldest remedies for epilepsy. It was recommended by Parkinson two hundred years ago, and has been perhaps for a still longer time a popular remedy for this disease in certain rural districts in the west of England. I have met with no case in which, given alone, digitalis arrested the fits for more than a few months, but in several cases it effected very distinct improvement. The combination of digitalis and bromide, however, was distinctly more useful than bromide only, in no less than sixty-three cases. In more than half of these, thirty-seven cases, the attacks ceased under its use, although they had continued under bromide alone. In the cases in which cardiac disturbance was associated the combination was almost always superior to bromide alone; but its use is not confined to these cases. Many cases of nocturnal and other forms of epilepsy yielded to the combination, although the attacks had continued under bromide, and this when there was no evidence of cardiac disease. I know of one patient with nocturnal epilepsy who, for two years, under this combination, has not had a single fit, although the attacks occurred every few weeks on bromide only.

In rare cases belladonna alone will arrest attacks. I have met with only one case in which attacks, which continued on bromide, ceased entirely when belladonna was substituted, and this was a case with hystero-epileptic symptoms. The combination of bromide and belladonna, however, was distinctly better than bromide alone in 35 cases, and in 15 of these arrest of the fits was thus obtained.

Indian hemp was first employed in epilepsy by Dr. Reynolds, and is sometimes of clear valu e. In one case the attacks were invariably arrested for many months by its use, recurring only when the patient ceased attendance, but twice on his resuming attendance the drug instantly arrested the attacks. When bromide was substituted for the Indian hemp the attacks at once recurred. Combined with bromide it is also sometimes useful, and seems to exercise most influence over attacks in cases in which there is persistent headache. The same fact has seemed true of the combination with gelseminum, which is occasionally of marked service.

The use of opium in epilepsy has long been advocated by Dr. Radcliffe, and in some cases it is certainly effective. The combination of bromide and morphia I have rarely found to present special advantages. In the status epilepticus in which attacks occur with great frequency and severity, and where bromide, even in large doses, was useless, I have found small hypodermic injections of morphia of great service.

The combination of bromide with aconite and hydrocyanic acid I have also tried, and found in some cases slightly better than bromide only. The addition of iodide to bromide has been lately said to increase its effect. Occasionally this is true, and in four cases of the series the combination was distinctly better than bromide only, but in many other cases it was ineffective. Even in the cases on the subjects of inherited syphilis it has not appeared of special value.

Zinc unquestionably deserves some of the repute it has enjoyed for more than a hundred years as an anti-epileptic. Of the cases of this series in which it was employed it was distinctly useful in ten, but in only three did the attacks cease. In three other cases attacks which continued under bromide ceased under bromide and zinc, and in a fourth they ceased under zinc, digitalis, and bromide. The oxide of zinc was the form commonly employed. Its nauseating influence constitutes a serious drawback to its use, as toleration is difficult to establish, and I have rarely succeeded in giving more than twenty grains a day. Bromide of zinc has seemed of small value, and is borne badly. The addition of arsenic to bromide in no case produced any marked effect on the attacks. It was used in a large number of cases on account of the readiness with which, it was found, the bromide rash could be prevented by its use.

Bromide of camphor, highly praised by Bourneville, was tried in a considerable number of cases, but without any good results. Turpentine has been recommended by Dr. Radcliffe, and I have seen it produce very striking benefit, but only in cases of hystero-epilepsy.

The use of iron in epilepsy has been discountenanced by high authorities, on grounds which are not altogether beyond question. In rare cases it increased the frequency of attacks; in the majority of cases in which it was used it was borne without any ill result; in many the addition of iron to bromide was attended with a marked and permanent improvement, and in some cases iron alone arrested the fits. The series includes 4 cases which ceased under iron only, and 8 others in which iron alone was distinctly better than bromide, and 19 cases in which the addition of iron to bromide exercised a marked influence. In no less than 11 cases attacks which persisted on bromide, ceased on the addition of iron, and remained absent as long as the treatment was continued.

In several inveterate cases of epilepsy in which bromide had no effect, I have tried borax. In some cases it did no good, but in 12 its value was most distinct. I may mention one or two. In one, fits which had continued on bromide and on zinc ceased entirely on borax for three months, and then only recurred when the medicine was discontinued. In another case the fits continued, about one weekly, during three months' treatment on bromide and on belladonna. Borax was then substituted, the fits at once ceased, and for five months the patient had not a single fit; then he had one in each of the two following months; the dose of borax was increased, and up to the present time, eight months later, no other attack has occurred. In a third case, one or two attacks occurred once a fortnight on bromide. Borax was substituted, and for five months the patient had not a single fit. The doses given have been ten or fifteen grains twice or three times a day. It produces in some patients gastro-intestinal disturbance, and rarely, a form of dysenteric diarrhœa. By others it is well borne, and one of my patients has taken forty-five grains a day for twelve months without the slightest inconvenience, and says that no medicine has ever done him so much good. In cases in which bromide fails, borax certainly deserves a trial.

The use of cocculus indicus in epilepsy, recommended by Dujardin-Beaumetz, has lately attracted attention in consequence of the recommendation of Planat. I have tried the alkaloid picrotoxine in a few instances, but in only one case has it appeared to do good. My own experience of its use has, however, been small, and I am very much indebted to my colleague, Dr. Ramskill, for permitting me to mention some interesting results which he has obtained by the hypodermic injection of picrotoxine. His experience of its effect on the fits when given through the skin is nearly the same as my own of its employment by the mouth. In seven cases in which it was injected, in daily doses of from one to four milligrammes, no beneficial result was obtained; in most cases, indeed, the attacks were rather more frequent and severe. Of course, we are not justified in assuming that the effect of picrotoxine and of the cocculus indicus itself are identical. A very interesting fact has, however, been ascertained by Dr. Ramskill—viz., that picrotoxine in larger doses of from fifteen to eighteen milligrammes will almost invariably produce a fit in twenty or thirty minutes. In one patient, for instance (according to the notes of Mr. Broster, who carried out the experiments), the dose was daily increased, and when more than five milligrammes were injected a sensation of giddiness followed, similar to that with which the attacks commenced. The same effect followed larger injections, and when the dose reached eighteen milligrammes a severe attack occurred thirty minutes later, and an attack always

Digitized by Google

followed the injection of this dose. In another patient a similar progressive increase of the dose was followed by giddiness and headache, when eight milligrammes were injected. When the dose of fifteen milligrammes was reached a severe epileptic fit followed. Next day a second dose of fifteen milligrammes did not cause a fit, but eighteen milligrammes, two days later, caused a fit in half an hour. After a week's intermission, twenty-four milligrammes were injected, and a severe fit occurred in twenty-five minutes. In a third patient a fit occurred after one injection of eight milligrammes, but ten milligrammes next day caused no fit. Fifteen milligrammes, however, were followed by a fit in thirty minutes, and a second injection of the same dose the following day caused a fit in fifteen minutes. Seventeen milligrammes next day caused a fit in thirty minutes. In a fourth patient a single dose of eighteen milligrammes caused, in ten minutes, giddiness and slight dazzling before the eyes, and in thirty minutes there occurred the usual aura of an attack—a sensation of something creeping up the right arm to the top of the head, and numbness and twitching in the right thigh, but no fit followed, although the patient was stupid and dull for a time just as after a fit.

Among other drugs which I have tried and found useless I may mention benzoate of soda and nitro-glycerine.

In hystero-epilepsy bromides, sometimes useful, fail entirely much more frequently than in simple epilepsy, and the combinations with digitalis and belladonna are also less frequently useful. Iron, especially guarded by aloes, is often of the highest value, quite apart from the existence of anæmia, and next to it valerianate of zinc, morphia, and turpentine.

High authorities have urged on different grounds that the diet of epileptics should contain little or no animal food. In a few observations which I have made by keeping a patient under unaltered medicinal treatment for alternate periods on a diet with and without animal food, I could observe no difference in the attacks, except that in one patient they were slightly more frequent in the periods when animal food was excluded, and in one patient hystero-epileptic attacks on ordinary diet became, when meat was excluded, severe epileptic fits, and again became hystero-epileptic when animal food was restored.

In pure epilepsy the only treatment needed during the attacks is such care as shall secure the patient, as far as possible, from injury. It is very different with the attacks of hystero-epilepsy, which, from their character, severity, and long duration, often furnish the attendants with a task of no small difficulty, and which can, almost always, be cut short by appropriate treatment. The patients often hurt themselves during the attacks, and some control is absolutely necessary. But, as already stated, restraint tends to increase the violence and makes the paroxysm last longer. Hence considerable judgment is often required, so to adjust control as to be efficient and not too much. I have seen these patients put within padded partitions and left alone, but I have never myself found this necessary.

The slighter attacks can be arrested by closing the mouth and nose with a towel for some thirty seconds, after Dr. Hare's method. The profound effect on the respiratory centre, and the related higher centres, caused by the anoxæmia, seems to arrest the convulsive action. Cold water over the head is often successful if applied freely; in severe attacks a moderate quantity only excites redoubled violence, while a second gallon is often more effectual than the first. This has the disadvantage of drenching the patient's head, and often giving cold. When the mouth is open during the attacks a small quantity of water poured into it is often effectual. A much more convenient and more effectual remedy than water, however, is strong faradisation to the skin; applied almost anywhere it will commonly quickly stop the attack. Of ovarian compression I spoke in the last lecture. In this country it is rare that ovarian pressure will arrest an attack. In some cases all these means fail, even when thoroughly used, and I have known such attacks go on, in spite of skilled treatment, for several hours. Chloroform is of little use; its administration is a matter of extreme difficulty, often impossibility, and the attack is commonly renewed when the influence of the anæsthetic passes off. The remarkable effect of nausea in relaxing spasm, led me some years ago to try the effect of injections of apomorphia, and I have found in it an unfailing means of arresting the attacks. After the injection of a twelfth of a grain in four minutes with certainty all spasm ceases, and normal consciousness is restored; in six minutes the patient will get up and go to the sink; in eight minutes will vomit, and afterwards, except for slight nausea, is well. A twentieth of a grain has the same action, but is rather longer in its operation. Moreover, I have found that the treatment is, so far as the hysteroid symptoms are concerned, curative as well as palliative, for the attacks in many cases ceased after a few paroxysms had been thus cut short.

I regret that in this survey of some points in the clinical history of these diseases it has been necessary to omit all reference to many facts regarding symptoms, diagnosis, and prognosis, which are presented by the series of cases analysed. I am conscious that as it is, in the details I have introduced, I have made a large demand upon your patience. But it is only by ascertaining the facts of these diseases that we can hope to learn their nature, or to find the guidance in our efforts at prevention or at cure.

Whatever may have been the nature of the demoniacal possessions of old, few who have watched an epileptic fit can doubt that they have their representatives among us still. The old power of casting them out has gone from the earth; and it is only by the study of their origin and history, and careful experiment in their treatment that we can hope to regain over them such power as may still be possible to man. And the present generation has witnessed an advance in the treatment of these diseases, equalled in perhaps no other branch of therapeutics. Thanks to the influence of one drug, the use of which in epilepsy is due wholly to Fellows of this College, hundreds of epileptics have been cured, and thousands are leading useful lives who would otherwise have been incapacitated by the disease. Although the condition of many sufferers is still gloomy enough, it is not without hope, and to them also, we may surely trust, the progress of the recent past is the dawn of a brighter day.

Lectures
ON THE
PHYSICAL EXAMINATION OF THE MOUTH AND THROAT.

Delivered to the Junior Class of Clinical Medicine, University College,

BY G. V. POORE, M.D., F.R.C.P.,

PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY COLLEGE; LATE ASSISTANT PROFESSOR OF CLINICAL MEDICINE; ASSISTANT PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE THROAT DEPARTMENT OF THE HOSPITAL, ETC.

LECTURE I.

THE PHYSICAL SIGNS DERIVABLE FROM THE BREATH, LIPS, TEETH, AND MOUTH.

GENTLEMEN,—It is my duty to bring to your notice the various physical signs of disease which are to be obtained from an examination of the throat and windpipe; but inasmuch as it is impossible to properly examine the throat without at the same time examining the mouth and nose, I think I shall be best fulfilling my duty by dealing methodically not only with the throat, but also with the oral and nasal cavities which lie above it.

The physical signs met with in these regions of the body appeal not only to the sight, touch, and hearing, but occasionally to the sense of smell as well; and the first thing which forces itself on our attention is often the odour of the breath.

The *smell of the breath* is a valuable physical sign, and in many diseases is so characteristic as to enable the man of experience to form a diagnosis from it alone with almost absolute certainty. It is impossible to describe the various odours of the breath; experience alone will enable you to distinguish one from the other, and I shall merely content myself with cataloguing some of the most distinctive of them. The smell of drink is the most common of all, and in cases of insensibility is often a valuable indication of the cause. It may give a valuable hint as

Digitized by Google

to the habits of the patient; and I would here remind you that over-indulgence in alcoholic liquors is one of the most common causes of congestion and catarrh both of the pharynx and larynx. You must not run too quickly to the conclusion that because a man's breath smells of drink he is necessarily a drunkard, for a single glass of wine or beer is sufficient to impart an odour to the breath for some time after it has been taken. When directing your attention to the alcoholic smell of the breath in the presence of the patient, I am in the habit of speaking of it as *oinosmia* (from *οἶνος*, wine, and *ὀσμή*, an aroma), since patients naturally resent having attention bluntly called to the fact that they smell of drink.

The presence of carious teeth imparts an odour to the breath which is quite characteristic, and which, according to Mr. Salter, resembles no other odour except that given off by the genus of neuropterous insects called Chrysopa. Want of attention to the mouth, and allowing food to lie between the teeth and decompose, or the presence of decomposing matters in the crypts of the tonsils, imparts a foul odour to the breath. A disordered stomach also causes the breath to be fetid.

A peculiarly disgusting and perfectly characteristic odour of the breath is present in those cases of chronic inflammation of the nasal and pharyngeal cavities, which are known from this fact as ozæna, and which are most often due to caries or necrosis of the nasal bones which is generally of syphilitic origin. The smell, however, may be present without any disease of the bones in cases of chronic inflammation of the cavities occurring in scrofulous subjects.

In cases of dilatation of the bronchial tubes accompanied by ulceration and copious purulent discharge, the smell of the breath is peculiar and almost diagnostic of the condition, and in gangrene of the lung the odour of the breath reaches a degree of foulness which once smelt can never be forgotten.

In cases of fever, with high temperature, a dry mouth, and the accumulation of sordes on the teeth and gums, the smell of the breath is peculiar. In pyæmia and in diabetes the breath has a sweet odour, but the odour in each of these diseases is perfectly distinguishable.

With inflamed gums the breath is apt to smell. This is peculiarly the case in patients under the influence of mercury, and the term mercurial odour of the breath is one in common use. In scurvy the breath is apt to be very foul. It is needless to say that certain articles of diet, as garlic and onions, and certain drugs, as turpentine, copaiba, and some of the essential oils, are detectable in the breath.

The *inspection of the lips* is capable of furnishing many facts which are of great service in forming a diagnosis. The *form* of the lips is characteristic in different races; thus the thick lips of the African negroes and the thin lips of most European races are well known. In conditions of general plethora the lips look swollen and big. A few cases have been recorded of great hypertrophy of the lips and neighbouring parts, a notable example being given by Mr. Barwell in the eighth volume of the Clinical Society's Transactions.

The *colour* of the lips is a matter of great importance. After great loss of blood the lips may appear of a waxy whiteness, and such an appearance should at once lead to questions likely to elucidate this point. A recent confinement attended by hæmorrhage is the most common cause of this appearance in women. Anæmia and leucocythæmia, arising from no matter what cause, produce a pallor of the lips, and in investigating cases of anæmia, we invariably look to the mucous surfaces of these parts. It is right to remind you, however, that undoubted evidence of hydræmia may be present without any very obvious alteration of the tint of the lips.

The lips are often unduly red in cases of general plethora and in the early stages of many febrile conditions. A cyanotic tint of the lips may be due to extreme cold, to those malformations of the heart which give rise to the condition known as cyanosis, and to a mal-aeration of the blood arising from no matter what cause, atmospheric, pulmonary, or cardiac. A patch of herpes on the lips (herpes labialis) is very commonly seen. It is a common accompaniment of an ordinary cold, and it is well to bear in mind that such an appearance may be indicative of more serious trouble, such as pneumonia. It is sufficiently often an accompaniment of pneumonia to make it incumbent upon us always to investigate this point when we are confronted with a patch of herpes on the lips.

In febrile conditions the lips get dry and cracked, and sordes accumulate upon them. Sordes are collections of dried mucus, evaporated saliva, and food particles, which cannot be removed, owing to the general dryness of the mouth and the paucity of the salivary secretions. This condition of the lips is seen in the most extreme degree in the state known as the typhoid condition, in which also the lips are often brown or almost black.

Round the margins of the lips are occasionally seen cracks, white lines, and little pits, the latter reminding one of the appearance known as the linea albicantes which occurs on the abdomen after pregnancy. These appearances occurring on the lips are sufficient to raise a suspicion of congenital syphilis. The other indications of syphilis which we may find upon the lips are: (1) a true infecting sore or hard chancre, which is happily rare; and (2) mucous tubercles, which may be present in cases of congenital or acquired syphilis. These mucous tubercles have the same appearance when seen here as when seen elsewhere—flat, slightly elevated patches, with a dirty-whitish surface, surrounded by a congested areola. Epithelioma is among the more rare diseases of the lips, concerning which one should be on one's guard.

The *movement* of the lips is a matter of great diagnostic importance. The muscular power of the lips may be impaired or abolished in several distinct conditions, such as hemiplegia, facial palsy, bulbar or labio-glosso-laryngeal paralysis, and general paralysis of the insane.

In hemiplegia the lip palsy is often slight, and in very slight cases which have partially recovered, a trifling drooping of the prolabium of the upper lip on one side, just sufficient to destroy the symmetry of the "Cupid's bow," is all that we can detect. The observation of this slight drooping and want of symmetry should always lead to an investigation into the history of the patient, and to questions likely to elucidate the question of hemiplegia. In marked cases of hemiplegia, and in cases of facial palsy from disease or injury to the trunk of the facial nerve, the paralysis of one-half of the lips is easily demonstrated, and on asking the patient to show the teeth it will be observed that the teeth are imperfectly exposed on the paralysed side, and the angle of the mouth is drawn over to the sound side. Facial palsy may be double, and then this want of symmetry is not observed, but the face is expressionless, and the teeth and gums cannot be exposed.

In bulbar paralysis the condition is usually bilateral, and the patient is quite unable to move the lips. In the later stages of this disease the lips waste, and the under lip droops so as to expose the gums and allow the saliva to run out of the mouth.

In general paralysis of the insane there is a paretic condition of the lips, and when they move they do so in a hesitating, jerky manner which is very characteristic.

In alcoholism the movement of the lips is also often tremulous. In chorea the lips are liable to those uncertain jerky movements which are so characteristic of this condition. In "muscular tic" one side of the mouth may be the seat of spasmodic movement. Lastly, in tetanus and spinal meningitis there occurs that condition which is called the risus sardonicus, which is caused by a spasmodic retraction of the angles of the mouth.

Dribbling of saliva is a symptom which is due to many causes. It may be due to an excessive secretion of saliva, a condition seen in cases of mercurial poisoning, and in some other states. It is present in cases where there is deficient movement of the lips and tongue, as in bulbar paralysis, or in cases where movement of the tongue is rendered impossible or painful by the presence of sores and ulcers. In patients also with whom the act of swallowing is impaired or painful, as in cases of paralysis or stricture of the pharynx, or inflammation of the tonsils or throat, dribbling of saliva is apt to occur. In children dribbling is a physiological condition, owing to a want of vigour and purpose in the movements of their lips and tongues, and in idiots this infantile condition would seem to be permanent. Old writers considered the dribbling of saliva to be characteristic of idiots and madmen.

An *inspection of the gums* occasionally affords important evidence of disease. Their *colour*, like the colour of the lips, may be pale or red or livid, and is an indication of anæmia or plethora or those conditions mentioned in connexion with the lips which give rise to a cyanotic tint. The gums are sometimes spongy and congested, and liable to bleed at slight causes. This is often the case in depressed conditions of health, arising from whatever cause. It is

Digitized by Google

present in a marked degree in persons who are under the influence of mercury, and to a less extent in those who are taking iodide of potassium. In leucocythæmia and in Hodgkin's disease the gums are often swollen and pale, and occasionally they are stated to become gangrenous. In purpura hæmorrhage from the gums is a common occurrence. In scurvy the gums are very greatly and remarkably affected. They become sore and apt to bleed at the slightest touch, and get swollen, spongy, and livid. The lividity is stated to be most marked at the free edges. The swelling of the gums is so great as occasionally to obscure the teeth, and in extreme cases they protrude between the lips. They get livid and almost black, and undergo sloughing and ulceration, which causes the breath to be peculiarly offensive. The sloughing may leave the crowns of the teeth exposed, and in such cases the teeth commonly fall out. Dr. Buzzard states that this condition of the gums is by no means invariably present in scurvy, and that all the other symptoms of the disease may be present in a marked degree, while the gums are not noticeably affected. Indeed, the gums in scurvy may occasionally be paler than usual and contracted.

A blue line upon the gum may, in the vast majority of cases, be taken as certain evidence that the patient is suffering to a greater or less extent from lead-poisoning. This "blue line" is due to a deposit of lead sulphide in the tissues of the gum. Dr. Hilton Fagge has made sections of the margin of a gum affected with a lead line, and by the aid of the lower powers of the microscope was able to see that the discoloration was not uniform, but was distributed in the form of rounded loops. The pigmentation was seen to be due to minute granules, and these granules were situated sometimes in the interior of the smaller bloodvessels, and sometimes outside them in the tissue immediately adjacent. The deposit is in reality black, its blue appearance being due to the fact that it is seen through a thin translucent layer of gum. Care must be taken not to mistake the purple congested edge of the gum of persons who do not clean their teeth for the deep blue line which is caused by lead. The blue line is produced by the action of hydrogen sulphide upon the lead which is presumably circulating in the blood. The hydrogen sulphide is produced by the decomposition of food particles lodging between the teeth, and adhering to the tartar. Persons who are careful to keep the teeth clean, and in whom no decomposition of the food particles takes place, may be suffering from lead-poisoning and yet have no lead-line upon the gums. The lead-line once formed, and being due to the deposit of an insoluble salt, may remain for months after the system has been freed from lead. Persons who have been exposed to the action of lead may exhibit no line upon the gums until after the administration of iodide of potassium. This is difficult of explanation, but the fact admits of little doubt. The blue or black discoloration caused by lead is not always limited to the margin of the gums, but may occasionally form black patches on the inside of the lips or cheeks.

Occasionally among the ill-fed and dirtily-kept children of the poor, and especially during the first dentition, the gums become swollen and the edges ulcerate, the ulcerated surface being covered with a dirty-grey secretion. This condition is known as gingivitis accompanied by offensive breath, and some increase in the flow of saliva.

The *teeth* often afford valuable evidence of constitutional conditions. Delayed dentition is apt to occur in children that are debilitated from any cause, but more particularly is this the case in rickets. Finding the dentition delayed, we should always search for other evidence of rickets. The milk teeth should begin to appear at the seventh month, and should be all "cut" by the end of the second year. The teeth appear in the following order—central incisors, lateral incisors, anterior molars, canine and posterior molars; and each of these five groups appears by the seventh, ninth, twelfth, eighteenth, and twenty-fourth month; the number of teeth which a child should have at the end of the months named being four, eight, twelve, sixteen, twenty. It may be some help to the memory to call attention to the fact that when a child is twelve months old there should be twelve teeth in the mouth. These numbers are liable to great deviation even in health. Some healthy children are precocious, while others are backward in the matter of dentition. The teeth may be wholly or in part deficient as the result of congenital defect. Caries or decay of the teeth is so common in this country that very few escape from it. It is more common in women than men, and is predisposed to by pregnancy and by the scrofulous and tuberculous constitutions. It is said to be caused by the generation of acid from the fermentation of food particles lodged between the teeth. There is a condition known as "rocky" enamel, in which the enamel of the teeth is grooved and pitted and honeycombed. This condition is brought about by rickets, or by any depressing illness occurring during dentition. Occasionally the teeth get excessively worn, so that they appear truncated, and the dental arch presents the appearance of a flat level border, the exposed dentine presenting a yellowish appearance. This condition, of which a very good sample was lately attending in my out-patient room, is rare, and is said to be predisposed to by syphilis, and to be favoured by the use of gritty food. Mr. Jonathan Hutchinson has pointed out that a peculiar condition of the permanent teeth often exists in patients who are the subjects of inherited syphilis. The incisors and canine teeth are small, peg-like in shape, narrow at the free edge, and either excavated by a crescentic notch at the margin or marked by a crescentic groove. The conical condition is most marked, according to Salter, in the lower, and the crescentic notch is most conspicuous in the upper incisors. When the teeth are lost very early in life, inquiry should always be made as to whether the patient has taken much mercury, and, if so, for what reason.

The *mucous membrane of the mouth* is sometimes swollen and red as part of a general catarrh. It may be swollen in consequence of gastric irritation, brought about by errors in diet. In children who are ill fed, and especially during dentition, small, circular, painful ulcers called aphthæ very frequently appear upon the gums and the internal surface of the cheeks. They are almost always an indication of gastric disturbance from injudicious feeding. When we get the mucous membrane of the mouth inflamed, and upon the inflamed surface a parasitic fungus (the oidium albicans) growing, we have the well known disease called thrush. The mouth, tongue, and palate and pharynx may be covered with white patches, and we may be in doubt whether these patches are due to curdled milk or diphtheria, but if a small quantity be placed under the microscope with a drop of caustic potash, the well known mycelium and spores of the oidium albicans are easily seen, and serve to clear up all doubts. Whether the fungus is the cause of the inflamed condition or whether the inflamed patches form a fitting nidus for the growth of the fungus is an open question. Thrush never occurs in well nursed children, and if a young child is fed upon good milk and nothing else, thrush seldom appears. When, however, mothers give farinaceous matter to very young children, often combined with milk which is slightly sour, this sticky mixture adheres to the inside of the mouth, and if the mouth be not very carefully cleansed out after every meal, the decomposing food particles irritate the mouth, cause it to inflame, and form a soil upon which the oidium grows luxuriantly.

Thrush is liable to occur in adults towards the termination of chronic illnesses, when they are too weak to cleanse their mouths by vigorous movements of the tongue. I have seen patches of thrush also occurring in a patient the subject of labio-glosso-laryngeal paralysis, because the movements of the mouth were too feeble for the purpose of properly cleansing it. The lesson to be learnt from these facts is that in feeble persons the mouth needs to be artificially cleansed after feeding by being sponged out with some antiseptic, such as a solution of borax, or, perhaps, there is nothing better than peppermint water, which to many persons is agreeable and refreshing.

ON LITHOTRITY;

WITH CASES ILLUSTRATING THE IMPORTANCE OF EARLY DETECTION OF THE STONE; AND STATISTICS OF STONE OPERATIONS IN THE HOSPITALS OF GLASGOW FROM 1795 TILL 1880.

BY GEORGE BUCHANAN,

PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF GLASGOW.

(Concluded from p. 523.)

NUMERICALLY stated, my experience is far too limited to be of any value; still I give it for what it is worth. I have performed lithotomy fifty-five times, with eight deaths, or one in about seven operated on, a proportion very similar to that obtained by examining tables of lithotomy at all ages,

Digitized by Google

and involving large numbers of operations. But when we separate cases under from those over puberty, the contrast is striking. Of the whole number, twenty-nine were over fifteen years of age, and the mortality after lithotomy in them was six, or one in five. There were twenty-six cases under fifteen years of age, and the mortality was two, or one in thirteen. On the other hand, I have had twenty-four cases of lithotrity with three deaths, or one in eight. Of these three, one died of apoplexy in twelve hours, some days after the stone was removed. The other two were, I confess, cases that should not have been operated on at all, either by one way or the other; the state of the patient and bladder being very unfavourable to any operative interference. This is just one of the difficulties a surgeon often meets with. His patient has arrived at a stage of suffering when life is unsupportable without relief, and he prefers to accept the remotest chance of success rather than to endure any longer the agony he is undergoing. In such circumstances lithotomy is very likely to be fatal, but if any operation is to be made, it ought to be selected. But these are just some of the cases which in the future will be the subjects of lithotomy, so that in proportion as lithotrity gains ground, and the suitable cases are chosen for it, in the same proportion lithotomy will become less frequent, and, being only reserved for cases unsuitable for lithotrity, will become more fatal.

It is clear, therefore, that the statistics of lithotrity ought yearly to become more favourable in consequence of being restricted to selected cases, while lithotomy will show a higher mortality than heretofore, in consequence of being performed only in cases unsuitable for the other. This must of course, even now, be taken into account in comparing extensive tables of lithotrity and lithotomy. But the concurrent testimony of all who have had large experience of both operations, as Civiale, Sir B. Brodie, Sir W. Fergusson, Sir Henry Thompson, &c., is decidedly in favour of the crushing operation.

Sir B. Brodie performed lithotrity 115 times, with a mortality of 1 in 12. Sir William Fergusson had 109 cases of lithotrity, with a mortality of 1 in 9. His mortality in adult lithotomy in 110 cases was 1 in 3⅓. Sir Henry Thompson, in 1878, reported 500 cases of stone operated on in the adult male—the total number of his operations up to that date. The total mortality was 1 in 8½. Of these, 78 were lithotomy, with a mortality of 2¾; the rest, 422, were lithotrity, with a mortality of 1 in 13. The total of these three operators is 646 cases of lithotrity, with a mortality of 53, or 1 in 12¼. These were all in adult males.

As a contrast, I quote Sir Henry Thompson's table showing the results of lithotomy as performed in a number of hospitals taken together. This table was compiled with the most scrupulous accuracy, all returns being rejected which did not specify the ages of the patients. The table contains 1827 cases of lateral lithotomy of all ages. The total mortality is 1 in 8. But when the cases under puberty are separated from those over that age the result is: under fifteen, mortality 1 in 15½; over fifteen, mortality 1 in 5.

I think therefore that it may be accepted as established that lithotrity is a very safe operation for all suitable cases; and that therefore it is of the utmost importance to detect the presence of stone at a stage when lithotrity is admissible—lithotomy being reserved for cases under puberty, and for stones which have by negligence been allowed to escape notice till they are too large to be safely dealt with by the lithotrite. Like all general propositions, this admits of some exceptions. In the case of very young boys with very small calculi the lithotrite may be used with safety, even though it be necessary to reduce the size by crushing before extraction. Again, in the adult the size of the calculus to be dealt with by the lithotrite must be decided by the composition of the concretion and the manual dexterity of the operator. But the details of these exceptions are too extensive for the scope of this paper.

I shall now illustrate some of the points in the two propositions by a few of the cases which have come under my care.

1. A stone may remain in the bladder for years without causing symptoms demanding an examination of the bladder, if that has not been done on the occurrence of the first symptoms.

In November, 1861, I removed by lithotomy two stones, together weighing 1¼ oz., from a boy aged eleven. Three years before he had for a few days very acute pain with passing of blood, but that passed off. Since then he had remained perfectly well till a few weeks before I saw him, when, after a long walk, the former symptoms came on.

2. A stone may be in the bladder for a long time, single symptoms recurring at long intervals, while during the intervening periods it may cause no annoyance at all.

Mr. —— while in London in the summer of 1871 noticed accidentally on one or two occasions a few drops of blood after passing water. He consulted his medical attendant, who took Dr. —— in consultation. They agreed that it was something accidental which did not require treatment. In a few days Mr. —— was quite well. In the summer of 1872, Mr. —— was again in London. One evening he suddenly experienced a desire to pass water with a sharp pain, shooting to the point of the urethra. On relieving himself he observed some blood as formerly. This occurred two or three times during the evening, but next morning he was better. He consulted another physician, who took a light view of his case, told Mr. —— to rest a few days, and have no anxiety. The symptoms passed off, and, as before, Mr. —— was quite well. In the summer of 1873 the same thing occurred in precisely similar circumstances. Mr. —— being a little alarmed this time went to a third physician, who hearing of what had happened formerly gave the same advice—rest for a few days before going back to Scotland, rest for a few days after the journey home. Again the symptoms passed off, and Mr. —— was as well as ever. In October, 1873, Mr. —— was out shooting, when the old occurrence took place—a sudden pain at the point of the urethra, intense desire to pass urine, some drops of blood at the end and after the flow. Mr. —— went to Dr. P. A. Simpson, whom he was in the habit of consulting, who at once suggested the probability of a stone, and asked me to sound him. I detected a stone the size of a Spanish nut. In November I removed it by lithotrity in three weeks, since which Mr. —— has continued in perfect health, and free from all urinary symptoms.

3. Symptoms of chronic cystitis may predominate to such an extent as to withdraw the attention from the necessity of examining the bladder to ascertain if the symptoms are not caused or aggravated by the presence of a stone.

M——, aged thirty-five, had suffered for several years from renal calculi, which caused pain in their passage to and from the bladder. For more than a year he was free from his complaint, but in the spring of 1872 the old suffering returned, and the urine was muddy. He took no account of it until he was on the eve of a visit to London, when he mentioned it to Dr. Fergus, his ordinary medical attendant, who warned him against delay in undergoing medical treatment, and advised him as soon as he got to London to put himself under the care of a medical practitioner whom he had consulted on former visits to London. He was treated for what he was told was inflammation and irritation of the bladder. His symptoms continued to get worse, and there was added occasional obstruction to the flow of urine. He was told that most probably there was a small calculus in his urethra which would come away as the former had done. He was advised to go to Harrogate and use the chalybeate waters before he returned to Scotland. But his symptoms getting worse he came away at once, and on his arrival sent for Dr. Fergus, who expressed his opinion that there must be a stone retained in the bladder. I visited him with Dr. Fergus, and we detected the presence of a stone. This I removed by lithotrity in three weeks, and the urinary symptoms rapidly improved. In a month M—— was walking about free from pain and trouble. The stone was about the size of an almond.

4. An examination of the bladder on the first occurrence of the symptoms detects the stone, when it can be removed with the greatest facility and safety.

Mr. ——, aged sixty-five, suffered from the passage of a renal calculus in 1867. Some time after there was difficulty and pain in passing urine. Now he consulted his medical attendant, Dr. Alexander of Dundonald, who sent him to me. I detected a small hard calculus. A few days after I went to his residence with Dr. Alexander to operate. With a thin-bladed lithotrite I grasped a stone, which I extracted entire, the urethra yielding to the steadily-applied traction. The stone was oxalate, about the size and shape of a damson stone.

Digitized by Google

W. G——, aged fifty-five, after a few months of inconvenience in passing urine, consulted Dr. James Adams, who detected a stone and sent him to my wards in the Royal Infirmary. On Feb. 21st, 1868, I performed lithotrity, and again on three other occasions. He was dismissed cured on March 8th. Weight of débris of calculus detected thirty-five grains.

5. Postponement of sounding allows the stone to grow to a size difficult and troublesome for lithotrity.

A. W——, aged twenty-seven, had urinary symptoms for more than a year before he mentioned his state to his medical attendant: pain, blood, muddiness of the urine. He was treated for many months with internal remedies, for what he was told was irritation of the bladder. Failing to obtain relief, he applied elsewhere, and he was recommended to go to Bridge of Allan and use the saline waters. Before going he consulted Dr. James Adams, who, suspecting stone, sounded him, detected the stone, and sent him to me. As the stone was larger than medium, it took from the 4th June till the 2nd July to remove it entirely. The débris collected weighed five drachms twenty-five grains.

6. When the bladder is fairly healthy and the urethra capacious, lithotrity is available for the removal of even large stones.

Mr. ——, aged sixty-five, suffered for many years from symptoms of stone before he consulted the late Dr. Fleming, who sent him to me. The stone was large and smooth, but I determined to crush it, as the urethra was large and not irritable. It took a month's time and repeated applications of the lithotrite to remove it, but it was successfully ended. The weight of the calculous matter collected was one ounce and one drachm.

7. When a very small stone is detected in the bladder of a child, it can be removed with ease and safety by a thin-bladed lithotrite.

In November, 1879, Dr. Crawford, of Uddingstone, brought to my house a little patient aged nine years, who had formerly passed uric-acid calculi. Now he was continually crying, and could not retain his urine. On sounding him, I found a small stone retained in the bladder. I put him under chloroform, and grasped the little stone in a thin-bladed lithotrite, and endeavoured to pull it through the urethra; but it was too large to leave the bladder. I therefore crushed it in pieces, some of which came away in the scoop, the rest were washed out with the first and second flow of urine.

The foregoing cases are ordinary examples of what are common occurrences; they are introduced, not as presenting anything new, but as good illustrations of the various points referred to in the two propositions with which I commenced this paper.

Statistics of the Operations for Stone in the Glasgow Hospitals.

The following *résumé*, though stated in a very few figures, represents an amount of labour which I had no idea of when I began, and which I could not have accomplished without the kind assistance of the house-surgeons in the Royal and Western Infirmaries, and particularly of Drs. M'Lachlan and Harkness.

The figures till 1859 are copied from a paper which I laboriously compiled, and published in the *Glasgow Medical Journal* for April, 1859.

From that date till 1870 the figures are taken from the printed annual reports of the Glasgow Royal Infirmary, the tables of which contain the numbers, sexes, and results, but not the ages. The ward journals and operation books during the period referred to are most imperfect; many have been lost; in others cases are omitted or not completed.

From 1870 till 1880 I have been able to make an accurate table. I first got all the cases collected from the hospital records, and submitted them to the surgeons themselves (except one who died in 1875), so that we have a clear starting-point for future statistics from Jan. 1st, 1870.

From the opening of the Royal Infirmary in 1795 till 1859 accurate records have been found of 159 cases of lithotomy in the male, with 23 deaths, or 1 in about 7 operations. Of these 95 were under fifteen years of age, with 6 deaths, or 1 in 15⅔ operations. There were 64 above fifteen years of age; of these 16 died, or about 1 in 5 operations.

From 1859 till Jan. 1st, 1870, there were 84 cases of lithotomy in the male, but the ages cannot be accurately ascertained; of these 8 died, or 1 in every 10½ operations.

THE DIAGNOSIS OF TUMOURS OF THE CEREBELLUM.

BY STEPHEN MACKENZIE, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN TO, AND LECTURER ON PATHOLOGY AT, THE LONDON HOSPITAL.

(Continued from p. 524.)

THE most valuable signs of intracranial tumour are headache, vomiting, and pain in the head, especially when associated with convulsive or paralytic affections. I cannot here discuss the qualifications as to the value of these symptoms beyond remarking that the seat of the headache bears no necessary relation to the seat of the lesion, that vomiting is not always a pronounced symptom in children, and that optic neuritis (though not absolutely conclusive) is the best evidence of the existence of some intracranial growth.

Assuming that the presence of these symptoms assures us of the existence of an intracranial tumour, it must be borne in mind that they tell us nothing as to its situation or nature. These have to be determined by other signs and symptoms. The most important signs of the location of a tumour in the cerebellum are—(1) a reeling gait, (2) tonic convulsions, (3) movements of the eyeballs, (4) enlargement of the head.

1. *Reeling gait.*—This is usually one of the earliest and most characteristic symptoms of cerebellar disease. The "cerebellar reel," or stagger, differs entirely from the walk in locomotor ataxy, and is most like the reel of a drunken man. I have known persons with cerebellar tumour to be accused of indulging. This reeling has been attributed by Dr. Hughlings Jackson to paresis of the spinal muscles. "The seemingly erratic action of the legs in some cases of cerebellar disease is for the preservation of the balance consequent on the spinal paralysis: the patients keep their legs widely apart, and, so to speak, their legs run after the trunk to underpin it in its various inclinings from side to side and from back to front." Later in the progress of the case the spinal weakness increases to such a degree that the legs are no longer able to prop up the trunk, and the patient becomes unable to walk or stand. At the same time all movements of the legs are preserved when the patient is in the recumbent position.

2. *Tonic convulsions.*—This symptom is of the greatest importance as distinctive of cerebellar disease. It may be broadly stated that clonic convulsion is associated with cerebral disease, tonic convulsions with cerebellar disease. The degree of tonic spasm met with in connexion with cerebellar tumours is variable. Sometimes it is limited to retraction of the head, as in Case 1. Usually with this there is extension of the spine—opisthotonos,—which in some instances, as in Case 3, is as extreme as in surgical tetanus, and the range of the two is so much alike as to afford the strongest reasons for the belief that tetanus is an affection of the cerebellum. The tonic contractions are not limited to the muscles of the limbs and trunk; when the convulsion is carried a stage further the legs are extended, often to an extreme degree, and the toes are turned in, whilst the arms are semiflexed and rigid, the fingers being tightly clenched upon the thumbs. In fact, the whole of the muscular apparatus concerned in locomotion is involved, and, as in extreme locomotory efforts, nearly every muscle of the body is brought into play, we find nearly every muscle rigidly contracted. Not only are the muscles of the trunk and extremities rigid, but the abdominal muscles are hard and board-like. In some cases the facial muscles are contracted, giving rise to the so-called "risus sardonicus." This tonic contraction is at first, usually, paroxysmal, the patient between the attacks being able to move the neck, trunk, and extremities. Later in the progress of the case there is permanent rigidity, the patient maintaining the "cerebellar position," but there occur paroxysmal exacerbations of the contractions. The reeling gait and tonic spasms are both expressions of disorder of the locomotory apparatus, of which the cerebellum is the chief governing centre. I shall discuss later how disease brings about its effects.

3. *Movements of the eyeballs.*—These are frequently observed in connexion with cerebellar tumours. The movements of the eyes are generally parallel, and may be upwards, downwards, horizontal, or oblique—most commonly the

Digitized by Google

latter. Sometimes they are only noticed during the convulsive attacks, when the eyes may be fixed in one or other direction, or may oscillate backwards and forwards in some particular direction. Later, when there is permanent rigidity, the eyes may incline strongly and persistently in one direction, with parallel oscillatory movements. These movements of the eyeballs from cerebellar disease are very interesting in connexion with the results of the experiments of Majendie, Ferrier, Hitzig, &c., and have important physiological bearings, Dr. Hughlings Jackson pointing out that the cerebellum contains processes of the eye movements and locomotor movements for estimation of distance.[1]

4. *Enlargement of the head.*—Though not invariably present, and when present not absolutely pathognomonic of cerebellar tumour, enlargement of the head, in association with the other localising symptoms, is a sign of the greatest value. The enlargement, in character, resembles that of hydrocephalus, being of exactly the same nature. The bulging is greatest above the ears, the forehead protrudes, the fontanelles open, and the sutures gape. The integument of the head becomes very thin and transparent, and the superficial veins are prominent (anastomosis?). The cause of the enlargement of the head is an internal hydrocephalus, as described at some length in Case 2. All the ventricles are found enormously dilated and deformed; full of fluid, generally clear, sometimes straw-coloured. The brain is squeezed out into a thin sac or capsule, containing the fluid: its substance is sometimes softened. The hydrocephalus is usually ascribed to pressure on the veins of Galen, which by increasing the lateral pressure on its radicles causes exudation of their fluid contents, in the same way that pressure on the portal vein causes ascites. It will be readily seen from the diagram, Fig. 4, that a tumour of the cerebellum, especially of its middle lobe—a favourite situation—will be extremely likely to compress the venæ Galeni. But I believe that whilst this may be a contributory factor in the production of the hydrocephalus, it is neither the sole nor essential one.

FIG. 4.

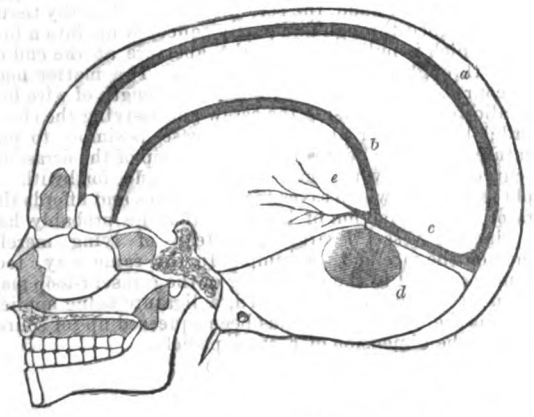

Diagram to show compression of veins of Galen by tumour of cerebellum, especially of middle lobe. *a*, Superior longitudinal sinus. *b*, Inferior longitudinal sinus. *c*, Straight sinus. *d*, Tumour beneath tentorium. *e*, Veins of Galen.

Granting that a tumour pressing upon the veins of Galen causes dropsy of the ventricles, as long as the outlet of the general ventricular cavity remains patent, as the fluid collects it will flow away. Moreover, if the pressure be extreme, it will cause obliteration of the vein. But it will readily be seen by reference to the diagram, Fig. 5, that subtentorial tumours, especially when involving the middle lobe, will be extremely likely to cause constriction or obliteration of the cerebro-spinal foramen or some point above this—the fourth ventricle or aqueduct of Sylvius. Such was certainly the condition in Case 2, where the medulla oblongata was strongly squeezed antero-posteriorly. I have seen the same condition in other cases. When the communication between the general ventricular cavity and the subarachnoid space is obliterated, the fluid poured out by the choroid plexuses, and possibly the obstructed venæ Galeni is dammed up, distends the ventricles, and causes the extreme hydrocephalus sometimes found. This view

1. Clinical and Physiological Researches on the Nervous System, p. 25.

was entertained by the late Mr. Hilton, and some instructive cases are mentioned by Wilks and Moxon.[2] As these authors remark, we see a like result brought about sometimes in chronic internal hydrocephalus. I recently made a necropsy in such a case, and found old and recent basilar meningitis glueing the membranes and obstructing the cerebro-spinal foramen. Some valuable observations on this subject have been made by Drs. Gee and Barlow.[3]

FIG. 5.

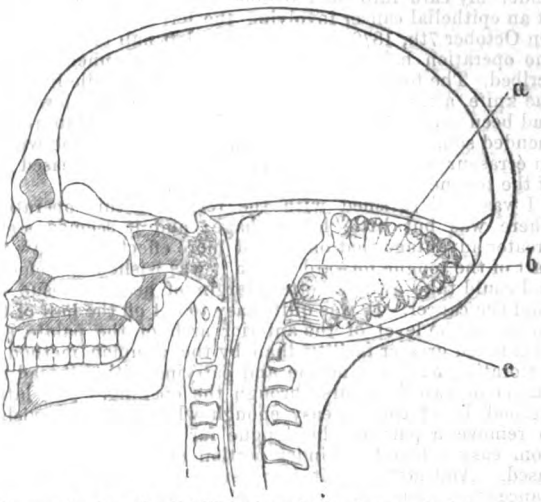

Diagram to show the liability of cerebellar tumour to interrupt the communication between ventricular cavities and subarachnoid space. *a*, Tentorium cerebelli. *b*, Fourth ventricle. *c*, Cerebro-spinal foramen. A tumour in situation of the cross would obliterate the cerebro-spinal foramen, above that point, the fourth ventricle.

The effects of this dropsy of the ventricles is very interesting and characteristic. The very gradual and equable (water) pressure to which all parts of the brain are subjected causes a gradual "blotting out" or dissolution of what mental faculties have been obtained, and the order of this blotting out is very instructive to the psychologist. From a conscious volitional being, the patient is reduced to a mere automaton, or to a vegetative existence. In this condition he may continue for a considerable time.

(To be concluded.)

ON REMOVAL OF THE TONGUE BY MEDIAN DIVISION OR SPLITTING.

By W. MORRANT BAKER, F.R.C.S.,

ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, AND SENIOR SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

A FEW years since I read with much interest in an address on Clinical Surgery, delivered in the University of Glasgow by Dr. George Buchanan, that he had found it a good plan, in removing one-half only of the tongue for cancer, to divide the organ in the middle line with the knife, after sawing through the lower jaw at the symphysis. Dr. Buchanan claims for this operation the advantage of being able to remove in many cases all the disease, and of saving, in part, those muscular attachments of the hyoid bone to the lower jaw, the complete severance of which had led to so much trouble in Mr. Syme's earlier cases in which he divided this bone as a preliminary measure to removal of the tongue.

It seemed to me, after reading Dr. Buchanan's paper, that the method of dividing the tongue in the middle line with the knife was capable of much wider application than to those cases only in which it was requisite to saw through the lower jaw. In other words, the use of the knife could be advantageously combined with that of the écraseur in cases in which the latter instrument had been hitherto used to the exclusion of the knife, on account of the fear of trouble-

3. Cervical Opisthotonos of Infants, St. Bartholomew's Hospital Reports, vol. xiv., p. 23.

Digitized by Google

some hæmorrhage. The anatomical fact that there is but a sparse anastomosis of the branches of the lingual vessels across the middle line of the tongue could be turned to good account, it seemed to me, so far as the employment of the knife was concerned; while the écraseur could be slipped, after division of the tongue in the median line, over the half which it was desired to remove and complete the operation.

I soon had an opportunity of performing the operation in the case of a woman aged thirty-seven, who was admitted under my care into St. Bartholomew's Hospital on account of an epithelial cancer involving the left side of the tongue. On October 7th, 1876, I removed the left half of the tongue, the operation being performed after the manner just described. The tongue was divided along the middle line with the knife, after its attachments in front to the lower jaw had been partially severed, according to the plan recommended some years since by Sir James Paget. The wire of an écraseur was then applied far back over the diseased half of the tongue beyond the seat of disease.

I was well satisfied with the result of this operation. There was but little hæmorrhage; and it seemed a still greater advantage that one could more effectually draw the part of the tongue forward which it was wished to remove, and could take away a better margin of healthy tissue behind the cancer. It was quite easy to cut off the half of the tongue at the level of the anterior arch of the palate, and with much greater facility than by the common method of perforating with the needle and carrying with a thread the chains of two écraseurs through the opening. The latter method is, of course, easy enough when it is not wished to remove a part of the tongue far back, but it is far from easy when the hinder portion of the tongue is diseased. And although it is possible under these circumstances to loop the wire or cord of the écraseur behind the disease with the help of curved needles thrust through the tongue behind the cancer, yet the loop when tightened up is almost certain to squeeze forward the needles; and the back part of the disease and not healthy tissue is apt, after all, to be crushed through, and a portion, therefore, to be left behind—a result which it is impossible to take too much care to avoid; for if there be one part of the body more than another in which a wide margin must be given to malignant disease, in an operation for its removal, it is the tongue. To remove only just so much of the organ as can be seen to be diseased with the naked eye is a useless procedure, so far as any long immunity from recurrence is concerned.

It may be well to mention here a few details, which render the performance of the operation easier, and may prevent some of the minor troubles which occasionally occur in the course of it. And I shall presume that a case is being dealt with in which the cancerous disease is extensive and reaches somewhat far back.

After the introduction of a suitable gag and the removal of any sharp or jagged teeth which might be in the way of the operator, two threads are passed through the tongue about an inch behind the tip and half an inch on each side of the middle line. The tongue being now drawn forwards and upwards, the frænum and, as far as it may seem necessary, some of the muscular attachments of the tongue to the lower jaw in front are now snipped through with strong, rather curved, blunt-pointed scissors, and the scissors are then "run" along the floor of the mouth at the side, beneath the mucous membrane, as far back as may seem requisite, keeping close to the lower jaw both for the avoidance of hæmorrhage and for the sake of being clear of the disease. The operator now with his forefinger clears the tongue in front and at the sides, and drawing it well forward again and giving one thread to his assistant while he holds the other himself, he cuts steadily along the middle line of the tongue from the tip backwards, and farthest along the mucous membrane. On the withdrawal of the knife, the finger is now again introduced, and it will be found quite easy to complete with it the median division of the tongue by a little tearing or splitting between the two halves. The only part which cannot be thus torn is the mucous membrane of the dorsum. Hence the advice just given to divide this with the knife as far as may seem necessary for getting beyond the level of the disease. The écraseur is now slipped over the diseased half of the tongue; the assistant turning the screw while the operator keeps the loop as far behind the disease as possible. This is, of course, one of the most important parts of the operation; any want of care at this stage being shown afterwards by the narrow margin of healthy tissue, or by none at all, left attached to the diseased mass. The insertion of curved needles behind the disease, in order to ensure the division by the écraseur of healthy tissue, is often advisable, but, for the reasons previously given, must not be considered a sufficient safeguard in the absence of free separation of the tongue's attachments in front and at the sides.

The écraseur employed should be one curved "on the flat," and a strand of twisted wire or strong whipcord will be found more serviceable than the linked chain, which, from working only in one plane or nearly so, is much less readily looped far back.

In all cases in which, from the extent of the disease backward, or in the floor of the mouth, any difficulty is anticipated in placing the loop of the écraseur well beyond the tumour, the cheek may be divided with advantage by an incision extending from the front border of the masseter to the angle of the mouth. This measure, indeed, though not uncommon, is, I am inclined to believe, much less frequently adopted than it might be, especially in cases in which the cancerous affection has invaded the floor of the mouth.

If combined with division of the frænum, and as much of the muscular structures which tether the tongue in front as may be safely divided, and if, at the same time, the mucous membrane of the floor of the mouth be cut through, so as to form a sound boundary-line for division in this direction, I have found that division of the tongue along its middle line is an excellent preliminary measure, not only in operations for removal of half the tongue, but of the whole organ also. The two halves are more completely under control than the tongue as a whole, and by working with two écraseurs simultaneously no time will be lost.

It sometimes happens, and especially when wire or whipcord is used instead of the jointed chain, that the portion of the tongue which has been noosed is not completely severed, even when the écraseur has been screwed up to the hilt; and this is much more likely to happen when the part of the tongue which is being divided is healthy than when the loop has been placed only just beyond, or not beyond, the diseased tissue. In the latter case the comparatively hard and brittle cancerous structure is easily crushed through; while, on the other hand, the soft and yielding healthy tissue is partly crushed through and partly squeezed up into a fine pedicle, which is pulled through the aperture at the end of écraseur through which the cord works. The matter may be, of course, remedied when too great a length of wire has been allowed, by reversing the screw and re-tying the chain or cord;[1] but a better plan in many cases is simply to put a ligature round the pedicle beyond the loop of the écraseur, and cut off the severed half of the tongue forthwith—a simple procedure, which saves many minutes and affords the operator the satisfaction of knowing that he probably has the principal vessel ligatured, instead of lying merely crushed on the face of the stump. In the same way, too, the time occupied in the tightening of the écraseur-loop may be often advantageously shortened, a ligature being applied so soon as the tongue-tissue has been squeezed up (of course slowly) to the dimension of a small pedicle.

(To be concluded.)

A MEDICO-TOPOGRAPHICAL REMINISCENCE OF THE WEST INDIES;

BEING CHIEFLY AN ACCOUNT OF THE HILL STATION OF NEWCASTLE, JAMAICA, WITH SPECIAL REFERENCE TO ITS CLIMATE AND ITS FLORA; IN CONNEXION WITH THE EXCEPTIONAL IMMUNITY FROM MORTALITY ENJOYED BY THE 29TH REGIMENT DURING THE YEARS IT WAS STATIONED IN THE COMMAND.

BY SURGEON-MAJOR BOILEAU, B.A., M.D.,
DIPLOMATE IN STATE MEDICINE, UNIV. DUBLIN, ETC.; ASSISTANT-PROFESSOR OF PATHOLOGY, NETLEY; AND FORMERLY MEDICAL OFFICER OF THE 29TH FOOT.

DURING a continuous residence of three years and three months in the West Indies, it was my good fortune to lose by the hand of death but one of the men entrusted to my professional keeping. The fatal case was that of a young recruit who died of acute hæmorrhagic phthisis a few months after landing from England. Such experience was all the

[1] An écraseur well adapted for this purpose has been constructed for my colleague, Mr. Harrison Cripps, by Messrs. Arnold, West Smithfield

Digitized by Google

more gratifying from the fact that there was no *primâ facie* reason to expect it, but quite the contrary; for the climate of the West Indies was until very recent years notoriously a most unhealthy one, and even the 84th Regiment, which the 29th relieved in Dec. 1869, suffered most severely. I shall dwell on two other factors adverse to favourable anticipations: first, that Newcastle, Jamaica, as an inhabited locality, is not 4000 feet above sea level, as it is generally represented to be; and secondly, that its climate is not temperate, as it has been described to be, but tropical.

Fifteen months of my residence in the West Indies was spent in Barbadoes in medical charge of the head-quarters of the 29th Regiment, the remaining two years in Jamaica, where for part of the time I was in charge of the whole regiment, and subsequently of a three-company detachment. I believe I am safe in saying that no regiment ever spent three years in the West Indies with so little fatality as the 29th Foot during the early part of the present decade. I shall endeavour to account for its immunity when I have concluded my remarks on the climatology of the station. I hope that my observations may be found of some value by those interested in the welfare of our troops abroad. It is interesting to know and profitable to reflect upon the fact, that the 29th Regiment, in the early part of the present century, was, in the very same quarter of the globe, in a few years almost annihilated by mortal diseases.

The military station of Newcastle, Jamaica, is situated on the Port Royal range of mountains, eighteen degrees north of the equator, seventeen miles from the sea, and about 3600 feet above it. From boreal influences it is quite protected by an amphitheatre of high hills, and it is of great importance to bear in mind that the station is not situated on an elevated plateau many miles from the lower lands, but that it is built on a hill ridge having very deep valleys on either side converging towards the south. The station is consequently exposed to the exhalations and other influences of a region the altitude of which is much less than 3000 feet above sea level. The air of these valleys is constantly swept upwards, and I might draw a very tropical picture of their vegetation, such, indeed, as might be expected of any place having the same altitude, latitude, and aspect.

The elevation of Newcastle is generally accepted to be 4000 feet above sea level, but in reality this is not the case, and a consideration of the height of the station is of importance in connexion with the fact that surprise is manifested when yellow fever invades the place. Only a very small portion of the cantonment is at or above 4000 feet. The quarters of the married people, and of the non-commissioned officers and men, are all below the altitude at which the hospital stands—viz., 3800 feet. Above 4000 feet the only occupation consisted of a few officers' quarters, the offices and the workshops of the Royal Engineers, and the garrison stables. Thus, more than nine-tenths of the inhabitants lived below 3800 feet. It is, therefore, evident that the old rule, an elevation of 4000 feet confers immunity from yellow fever, is not invalidated by the occurrence of the disease at Newcastle, Jamaica.

The whole station commands towards the south a widely extended view, stretching over the lower range of hills, with the plains of Mona, and of Liguanea beyond, and farther off the Caribbean sea, bounded by the horizon, eighty-three miles distant. The semicircular range of hills which within a couple of thousand yards northward of the station half encompasses and protects it, culminates in St. Catherine's peak, a summit which rises to the height of 5000 feet above sea level.

The buildings consist of wooden huts, well constructed and well ventilated, and well exposed to light, in which very important respect no station could be more favourably situated.

I will not dwell on the geology, the physical geography, or the natural features of the place. A perusal of Sawkins' "Geology of Jamaica" will repay those interested in such subjects. The useful mineral products of the place are almost nil, even stone for building purposes being procured with difficulty; it is required for the construction of foundations and for the strong retaining walls, without which the station would soon be swept away by the tremendous rains which occasionally deluge it.

The flora of the place may be studied in Grisebach's "Flora of the West Indies," or in Macfayden's "Flora of Jamaica." The learned professor of Göttingen, whose work has been published under the auspices of the Secretary of State for the Colonies, laboured under the apparent disadvantage of never having been in the West Indies; a fact hardly to be suspected, so accurate are his descriptions of its plants. Macfayden's work was never completed; it is difficult to procure. A work published by Dr. D'Anzer about the beginning of the century contains an interesting account of all the plants of the island reputed for their curative powers.

The vegetable productions of the immediate neighbourhood of Newcastle include the following:—Coffee. Yam; the edible tubers of which are largely used in place of potatoes; it is a species of *Dioscorea*. Bananas; plantains; sweet potatoes, or tubers of the *Ipomœa Batatas*, a convolvulaceous trailing plant. Oranges; limes; lemons. Various herbs of the *Brassica* family. Ochra (*Abelmoschus esculentus*), a malvaceous herb, the capsules of which contain a nutritive mucilage, much used in soups. Cherimolia, and several other most agreeable fruits of the custard-apple order. Melons, mangoes, pine-apples, and the Avocado pear, a fruit much esteemed, and known as "subaltern's butter"; the tree which bears it (*Persea gratissima*) is a species of *Laurineæ*. The myrtle family provides guavas, allspice, pomegranates, and rose-apples (*Jambosa vulgaris*). The allied family *Melastomaceæ* yields the American gooseberry (*Heterotrichum patens*), and the *Rosaceæ* supplies blackberries and strawberries in abundance. The winter cherry, better known as the Cape gooseberry (*Physalis Peruviana*), grows wild; it is an agreeable subacid fruit, resembling our own grossularia, but it belongs to a very different order—viz., *Solaneæ*. The tobacco plant attains a height of five or six feet, and flowers freely. The annual thorn-apple (*Datura stramonium*) flowers a little below the station, whilst its arborescent relative, the *Brugmansia*, or *Datura suaveolens* of Peru, is the commonest of all plants about the cantonment; it is known as the "bell-flower," and is often mistaken for another "bell-flower," the *Solandra grandiflora*: the latter is, however, a scandent plant, with terminal flowers. The castor-oil plant is quite common, and the showy bracts of *Poinsettia pulcherrima* are perhaps the most conspicuous objects on the hill. Another of these equinoctial spurgeworts which thrives there is the *Euphorbia splendens*, an obnoxiously-spiky plant, and one that has a fitting companion in the *Cæsalpinia horrida*, a most prickly shrub introduced from the East Indies for growing fences.

Amongst other well-known medicinal plants that the climate suits is the *Cissampelos pareira*, most appropriately called "velvet leaf." I found it forcing its way through the tangled mass of under-shrubs, which contend for existence below the Warwickshire-road. Growing near it I found an annual herb, which the negroes call "semencontra;" it is not, however, an *Artemesia*. It is *Chenopodium ambrosiodes*, sometimes known as Mexican goosefoot. It is reputed to possess anthelmintic powers. The arnotta (*Bixa orillana*), which yields the well-known dye, may be found just below Newcastle, and indigo grows abundantly in its immediate vicinity. Cardamoms ripen their seeds, and wild ginger (*Canna*) abounds so as to be a perfect nuisance. Yuccas flower, and bamboos attain a height of twenty-five or thirty feet. Guinea-grass (*Panicum maximum*), an excellent food for horses, and Bahama-grass (*Cynodon dactylon*), equally good for cattle, might be extensively grown. Foxtail-grass (*Anatherum*) reaches the height of five or six feet, and is, I believe, prized for thatching purposes, in consequence of its enduring properties. Lemon-grass (*Andropogon Schœnanthus*) abounds. The natives make an antipyretic and diaphoretic drink from it. Its odour is very agreeable and powerful; in fact, it is one of the three most strongly-smelling plants of the hill, the second being *Micromeria obovata*, a common wild labiate shrub, known also as *Zygia aromatica*, and smelling powerfully of peppermint, and the third is a most fragrant, yellowish-flowered plant belonging to the *Scitamineæ*, and which, I presume, is *Hedychium coronarium*, or the sweet-smelling garland flower.

The fauna of the station I will not dwell on. It may be studied in those two excellent works of the accomplished naturalist P. H. Gosse—viz., "Birds of Jamaica" and "A Naturalist's Sojourn in Jamaica."

The climate of Newcastle is equable; and, as far as our experience enabled us to judge, very healthy; but the sad experience of other regiments prove how foolish it is to generalise concerning any place, even after a three years' residence. The 29th Regiment did not lose a single officer, man, woman, or child from any disease attributable directly

Digitized by Google

or indirectly to climatic, epidemic, or endemic causes. We had, it is true, some fifty cases of fever amongst the men alone during our first year at the station, and many more subsequently, but all did well, not even one being invalided. Whilst Clotho and Lachesis were busy, Atropos slumbered.

The annual rainfall at the station is large. I have measured twelve inches in one day; yet, although the place may be said to be in the region of clouds, the climate is not always damp. Generally speaking, a cloudless sky was constant between sunset and 9 or 10 o'clock the following morning; rain during the night was an uncommon occurrence. The permeable and absorbent soil and the sloping declivities contribute greatly to the prevention of a humid atmosphere. The upper part of the station is certainly more moist than the lower, as may be inferred from the fact that ferns of the *Hymenophylleæ* tribe may be gathered in abundance a little above the cantonment and the upper huts, whilst in the neighbourhood of the lower ones none can be found. The barometric column varies little. At the highest point of the station it stands about four inches lower than at the sea level. The reaction of the ozone papers I frequently found to be near the maximum. The electrical state of the atmosphere varied extremely. In one year disturbances were constant and often very great, the storms being occasionally exceptionally severe, whilst in another year the sound of thunder was heard but seldom. On the 15th September, 1870, there occurred an unusually magnificent thunder-storm. On the 17th and 18th of the following November there was a very large rainfall—viz., eighteen inches. The damage to the station caused by this flood cost upwards of one thousand pounds to make good. The direction of the wind was variable, but generally from the north-east, as might be expected from the latitude of the place. Currents blew up and down the gullies, and in and out of the passes in all directions, so that it is only by observing the movements of the clouds that the prevailing direction of the wind can be ascertained.

(To be concluded.)

FRACTURE OF SPINE FROM DIVING INTO SHALLOW WATER.

BY J. H. WILSON, M.R.C.S., L.S.A.

A BRIEF record of the following case may be read with interest:—

P. S——, aged eighteen, a pupil at the Oundle Grammar School, whilst bathing on July 15th, 1878, took a header into between three and four feet of water. It being observed that he did not rise to the surface, the attendant (who is always present to look after the safety of the boys) dived in and fetched him out in a state of insensibility. After a few moments he rallied from the concussion and was conveyed home perfectly sensible, but helpless.

Examination revealed complete loss of motion and sensation of the lower extremities and the trunk up to two inches above the mammary line, with great pain over the cervical vertebræ, inability to support the body in the erect position, or move the spine in any way. No displacement of the vertebræ could be detected. There was partial paralysis of the upper extremities, and sensation was more pronounced on the ulnar than the radial aspects of the arms. There was retention of urine with priapism; *breathing almost entirely diaphragmatic.*

The usual treatment for fractured spine was carried out—skilled nurses were obtained; every possible attention was paid the patient to promote recovery.

At first there was considerable constitutional disturbance: pyrexia, loss of appetite, &c.; periodic attacks of dyspnœa, complicating the diaphragmatic breathing; ammoniacal urine (catheterism being continued). This condition of things was followed after a time by sloughing of tissues, which progressed steadily to the termination of the case. For five months we had to compete with severe bedsores, wholesale sloughs, disintegration of the knee-joints, the attachments of which became quite disorganised, and other signs of low vitality, the patient succumbing to his injury on Dec. 24th, or twenty-three weeks after the accident.

Post-mortem.—At the autopsy on Dec. 26th the fifth cervical vertebra was found to be fractured vertically through the body. The fracture had apparently partly united towards the posterior part of the spinal canal. Spinal cord at this point was reduced to a mere slender thread, only a few fibres remaining by which either motion or sensation could be conveyed.

The points of interest in the case are: (1) the position of the fracture—vertically through the body; (2) the length of time the patient lived, taking into consideration the seat of the fracture and the severity of the injury to the spinal cord.

GUY'S HOSPITAL.

[OBSTETRIC WARD.]

TWO CASES OF RETENTION OF URINE; REMARKS.

(Under the care of Dr. BRAXTON HICKS.)

CASE 1. *Enormous Distension of Bladder; Retroversion of Uterus; Pregnancy three months and a half; Œdema of Vulva and Lower Extremities, ceasing on Catheterisation; Restoration of position of Uterus; Recovery.* (From notes taken by Mr. J. Poland, obstetric resident).—A. F——, aged twenty, had a child in April, 1878. In April, 1879, she ceased to menstruate. In October following, about a month before admission, she fell down on her face and abdomen, and was much shaken, and about a week after the abdomen increased. She had some medicine and got better, but about a fortnight before admission the abdomen again began to swell, and it remained enlarged at the time of admission. She had suffered from the uneasiness and tension, but within a few days the urine had been scantily passed.

On admission, the abdomen was distended as large as in the eighth month of pregnancy, but it was more tense, and the skin was shiny. The vulva and legs were œdematous. On examining per vaginam a firm swelling was found to the posterior part of the pelvis, the os uteri being close to the symphysis pubis. A catheter was passed, and 146 ounces of urine were drawn off, thereby removing the swelling above the pubes, but showing more plainly that in the pelvis, which rose somewhat, and was evidently the pregnant uterus. In ten hours, however, the bladder had enlarged again, and 120 ounces of urine were drawn off; *four hours* after seventy ounces; in three hours and a half, fifty ounces; and at the end of the twenty-fourth hour, forty ounces more, making altogether in the twenty-four hours over twenty-one pints, of which fourteen were actually secreted in the twenty-four hours. The woman was kept in bed, and shortly the œdema subsided. An air-ball pessary was placed in the vagina, and kept in position by a bandage and pad outside. She was kept prone as much as possible, and the uterus by the second day rose into the abdomen, and there continued. No further trouble occurred.

Dr. Hicks remarked that it was seldom, if ever, the distended bladder had been found so large, or producing such an effect, as in this case. He said that the history made the diagnosis easy, assisted by the catheter, which should in all cases of tumour of the lower abdomen be passed as a matter of routine. He cited a number of cases where the employment of this rule would have saved mistakes, for in these cases complete retention seldom occurs, and then a small quantity passing, it is not considered that any is retained. The passing of the catheter makes this matter clear. Dr. Hicks remarked that it is not always an easy matter for beginners to find the meatus urinarius, nor when found to get the instrument into the bladder. He had generally found the urethra drawn upwards, and so the meatus was behind the symphysis pubis, and he had found that when the point had entered the handle should be carried backwards

Digitized by Google

close to the perineum as it was passed in; indeed, this movement generally caused it to pass into the bladder.

He also said that he had found the air-ball pessary sufficient to restore the uterus in such cases; it was gentler in its operation than any other, though sometimes the keeping the patient in bed, in the prone position, and keeping the bladder fairly empty for a few days, were generally sufficient. It was an interesting feature in this case that, with such severe distension of the bladder, no inflammatory symptoms followed; neither was there any decomposition of the urine, which was also healthy in all other respects. It formed a strong contrast with those cases of retention following labour, where, after twenty-four to forty-eight hours, extreme purgency of the urine takes place, with severe cystitis. In these probably the cystitis is the result of the bruising of the tissue of the bladder. Dr. Hicks said that he had not been able to detect any alternation in the tension of the bladder-wall when distended, such as occurs in the pregnant uterus, nor had he in other similar cases. As this was the only other organ which might have done so, he said that up to the present time the alternating contractions and relaxations of the uterus may be held diagnostic of distension of that organ.

CASE 2. *Retention of Urine from Pressure of a Descending Fibroid; Excessive Vomiting; Aphthous Mouth; Death.*—This case occurred in an Irishwoman, about forty years old, admitted into Mary ward extremely ill, with very quick pulse, high temperature, and excessive vomiting. The mouth was covered with aphthæ, and the body emaciated. There was a *hard* firm tumour above the symphysis, extending half-way to umbilicus, and subfluctuating. Per vaginam there was a large mass above, which so firmly filled the vagina that at first sight it appeared like a solid infiltration of the upper part of the canal; but after some trouble the finger was found to pass by the side of the mass, which ultimately proved a fibroid tumour, having a polypoid shape. Offensive grumous secretions escaped during the examination. The tumour above the symphysis seemed at first sight to be attached to the vaginal tumour, and to be firmly fixed in the pelvis. This appearance was increased by the unyielding nature of the abdominal swelling, which seemed of the same consistence as an ordinary fibroma of the uterus. But by following Dr. Hicks's invariable rule of passing a catheter, this tumour was found to be the distended bladder, from which was drawn about forty ounces of urine, upon which the swelling disappeared.

As the patient was too ill then to bear an attempt to remove the fibroma, attention was paid to lessening the irritation and removing the ichorous offensive discharge by antiseptic lotions. This treatment was, in a week, so far successful that the vomiting and irritative fever had ceased, and she was placed under chloroform for operation. As the vaginal tumour could not be removed *en masse*, it was attempted by écrasement, but the instrument was damaged before the whole growth was removed, and the rest had to be removed two days after. After these operations, however, either by the disturbance locally or by the anæsthetics, vomiting returned, collapse came on, and the woman died about the fifth day.

As no post-mortem examination was permitted, the exact cause of death could not be ascertained; but it was thought that not improbably some of the symptoms were owing to pressure on the ureters, which effect was not infrequently found to arise in similar cases. However, Dr. Hicks drew especial attention to the condition of the bladder, which was hard and firm, thereby presenting a strong contrast to the case above, and much more liable to deceive. In this instance this firmness did not intermit with any relaxation, nor was there any special symptoms of retention of urine.

WESTMINSTER HOSPITAL.

GANGRENE OF THE LUNG; RECOVERY.

(Under the care of Dr. STURGES.)

FOR the following notes we are indebted to Mr. Charles Hibbert, clinical assistant:—

Stephen M——, aged twenty-seven, a barman, was admitted into Burdett ward on the 7th October, 1879. He had rheumatic fever when a child, but no other illness previous to the one complained of. Five weeks before admission he had been much exposed, and caught cold, complaining of cough, pain in the left side of the chest, profuse expectoration, and dyspnœa. These symptoms became more marked, and the patient also complained that his breath and sputa were very offensive, and that the dyspnœa frequently came on in severe paroxysms.

He was very anæmic in appearance, and seemed very weak, having lost flesh considerably. His breath and sputa were of the characteristic odour of pulmonary gangrene; the fetor was so intolerable as to make it most difficult to approach him, and was noticeable throughout the ward. The sputa were frothy at the surface, but had a blackish-grey layer below, the sputa having the same odour as the breath. On percussion, there was a patch of dulness over the left base behind, about three inches square, and on auscultating over this patch crepitation of medium character was heard during inspiration and expiration. The other parts of the lungs gave evidence of bronchitis.

Dr. Sturges diagnosed the case as gangrene of the lung, and ordered the patient to be placed in a complete atmosphere of carbolic acid vapour. A tent was placed round the bed head, and vapour of carbolic acid was passed into the tent. The strength of the solution was one per cent. One drachm to half a pint of water was used for vapouriaing, and then gradually strengthened.

The patient was kept in this atmosphere for five weeks; for the first fourteen days the symptoms of cough and dyspnœa were no better, but the offensive odour of the expectoration disappeared; sputa still giving evidence of pulmonary breakdown. During the remaining three weeks of this treatment the symptoms gradually improved, and the patient became better and stronger, and increased in weight.

On November 12th he was examined, and it was found that the physical signs at the left base had much improved, the breathing being fairly healthy. The sputa were no longer black and offensive.

On the 20th the patient was discharged in fair health.

There was nothing to remark about the temperature; the diet was mainly milk, beef-tea, and light puddings; meat during convalescence. The carbolised vapour had evidently prevented the gangrene from spreading after the slough had been thrown off in the sputa; the lung gradually regained its normal character.

GENERAL INFIRMARY, HEREFORD.

SUB-ACUTE SPINAL PARALYSIS OF ADULTS (POLIOMYELITIS ANTERIOR).

(Under the care of Dr. BULL.)

FOR these notes we are indebted to Mr. Charles Davis, house surgeon:—

W. W——, aged thirty, a shepherd, married, father of two children, was admitted on Feb. 24th, 1879. The patient was a well-developed, healthy-looking man of sanguineous temperament, and possessed of more than average intelligence for the class to which he belonged. His family history was good, without evidence of nervous disease. He had himself always been strong and healthy until the present illness; temperate, not syphilitic, nor given to venereal excesses. He had lived fairly well, but had been much exposed to the weather.

On admission he had total loss of voluntary motion in the upper and lower limbs, back, neck, and abdomen, and impairment of the muscles acting on the lips. There was no paralysis of the bladder or sphincter ani. Reflex action, including the tendon reflexes, was entirely wanting. There were no muscular contractions, fibrillar or otherwise. The muscles were soft, flabby, and considerably diminished in volume, by comparison with a healthy subject of the same build. Sensation was everywhere perfect, the points of compasses being detected at normal distances with great precision. There were no paræsthesiæ of any kind; cold and heat sensations being correctly distinguished, and no constricting band or tenderness to bedsore. There was decided defect in pronunciation of labials, but no difficulty in swallowing. The fundus oculi was healthy, but the pupils were rather sluggish. Electro-muscular contractility to both galvanic and faradic currents was entirely absent in both upper and lower limbs. Pressure, heat, and cold elicited no spinal tenderness. The urine was ammoniacal, containing copious catarrhal deposit. The bowels were variable; skin moist and warm. Temperature 99·2° F.

Of the onset of his illness the patient gave the following account:—Early in February last he was exposed to severe

Digitized by Google

cold and wet for twelve consecutive hours, getting very cold and numbed. On returning home he soon regained warmth, his feet feeling all right, but his hands were very stiff and numbed. He had no shivering or pain. On attempting to walk he found his left leg weak at the knee, and his calf a little painful. He slept well during the night, and on waking next morning he felt stiff and sore all over, not being able to move his limbs properly. He could walk across the room, but with much stiffness of the legs. He was unable to grasp anything firmly, or to button his clothes. He returned to bed, and whilst there found the stiffness and weakness increase, and by the same evening was unable to stand without support, his knees and hips bending beneath him. On the following morning he could not move his limbs in the least, and on the day after—the fourth from the day of exposure—he could not raise his head from the pillow, and lay quite helpless. At about the tenth day retention of urine occurred, and he lost control over his rectum, its contents escaping involuntarily. This last symptom only lasted two days, and the retention of urine a few days longer. The urine, which was drawn off by a catheter, was very thick and sticky, but no blood was ever passed. He never had any loss of sensation, nor any feeling of numbness, formication, &c. He had no pains in the limbs, and could always recognise the pressure of the bedclothes and of his book-rest. He had no cramps or spasms of the muscles, nor any trembling. He did not suffer at any time from headache or pain in the back. He stated that he felt quite warm throughout his illness, sweating profusely at times, but never feeling chilly. His secretions were always active. He had lost a great deal of flesh. His general health did not suffer in the least.

April 11th.—The patient was able to perform the following movements: arching of the spine between the shoulders and the hips, slight raising of the head from the pillow, drawing the legs up by acting from the abdomen on the pelvis, slight shrugging of the shoulders, and slight extension of the fingers; the improvement in muscular action being in the above order. Electro-contractility was reappearing in the forearms, but not in the lower limbs; the reaction being to galvanism, but not to faradism. A few days before he developed inflammatory conditions of the nail matrix on those fingers only that were exposed to the friction of the bedclothes—viz., the thumb, ring and little fingers of the right hand, and the ring and little fingers of the left hand. This condition came on before ergot, which was ordered, was given.

On the 19th, mobility in the forearm, muscles, and flexors of the elbow-joint had much improved, galvanic excitability in these having increased. The lower limbs showed no improvement. The toes were becoming much pointed, partly from the weight of the bedclothes.

On May 2nd there was great improvement in the upper limbs; extension of fingers being most rapidly advanced towards recovery; some signs of extension of toes and flexion of knee-joint. The reaction to galvanism was much greater in the upper limbs, slight in the thigh, and absent in the legs. Faradism produced a just perceptible contraction in the forearm extensors, and this only with the strongest current obtainable.

From this time until June 14th, when the patient left the infirmary, the limbs continued to improve slowly, the upper limbs by far the most, and on his discharge he was able to raise his hands above his head, though flexion and extension of the fingers were yet very imperfect. The improvement in the lower limbs was most marked in the flexion of the knee-joint. Reaction to galvanism still improving, to faradism still very slight, in forearms only.

As regards treatment, until April 10th the patient took iron and strychnine without apparently any effect. On that date the liquid extract of ergot in fifteen-minim doses was given three times a day, with belladonna in addition to the former drugs, the ergot being subsequently increased to twenty-five minims each dose on May 3rd, and thirty minims on May 13th; this dose being continued until June 14th without producing symptoms of ergotism. Active counter-irritation was employed along the spine with galvanism (thirty cells of Stohrer's battery), the current being passed from the nape of the neck to the sacrum, and from the sternum to the spine. Faradism was applied to the muscles.

The patient continued to progress uninterruptedly towards recovery, and had no abnormal sensations of any kind. On Jan. 7th, 1880, he was in good health, had gained in flesh, his muscles being larger and firmer than when he left the infirmary in June. He could walk a considerable distance with the aid of a stick in each hand, he was able to use his upper limbs well, and could write a fairly good hand, and was capable of a considerable amount of muscular resistance, the chief defect being in the muscles acting on the ankle joint and toes. There was still evidence that great wasting had existed. An electrical examination showed that the faradic irritability was still very low, especially in the lower limbs. A galvanic current of thirty cells only produced moderate contraction in the forearms and feeble contraction in the legs; in addition the anodal closure contraction was quite equal to that of the cathodal closure, AnSZ = KaSZ being the formula for the forearm muscles, and AnSz = KaSz that for the leg muscles. Reflex action of lower limbs was still very low; no tendo reflex (patellar and tendo Achillis) could be elicited. There was a slight tendency to talipes equinus from the contraction of the calf muscles, and there was also some hyper-extension of the knees when the patient was on his leg.

Remarks.—The diagnosis of sub-acute spinal paralysis rested on the marked absence of constitutional disturbance, of cerebral symptoms, of pain in the back, and of disturbances of sensation, all of which occur in the acute form of the disease, on the rapidly-increasing paralysis of almost all the muscles of the body, with their subsequent rapid atrophy, with loss of their electric excitability, and, further, the comparatively rapid recovery of muscular action accompanied by the increasing and qualitatively altered galvanic excitability, the reaction to faradism still remaining almost *nil*.

In two points the case much resembled the acute form of the disease—namely, in the very rapid though progressive onset of the paralysis, and in the disturbance of the bladder and rectum. An interesting feature of the case was the undoubted causal relation to the attack of severe exposure.

The completeness of the recovery was somewhat remarkable, as was also the absence of general disturbance in such a rapid onset of a profound alteration of nerve-tissue. Of the incontinence of fæces no mention of a similar condition seems to be made by the authorities.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Molluscum Contagiosum.—Elephantiasis.—Horny Growth.—Recent Division of Tendo Achillis.—Calcareous Tumour in Peritoneal Cavity.—Melanosis.—Old Excision of Knee.—Disease of Larynx in Congenital Syphilis.—Spinal Cord in Tetanus.

THE ordinary meeting of the Pathological Society was held on Tuesday, the 6th inst., J. Hutchinson, Esq., in the chair. Professor Ball of Paris was unanimously elected an ordinary member of the Society.

The first business of the meeting was the reading of a report of the Morbid Growths Committee on Dr. Abercrombie's specimen of Tumour of the Skull, by Mr. R. J. GODLEE, who, with Mr. Marcus Beck, had examined the specimen. The report showed that the tumour was a "round-cell sarcoma," growing from the deeper layers of the periosteum and dura mater, not from the bone.

Mr. STARTIN showed some drawings of a case of Molluscum Contagiosum, and of the microscopical appearances he had observed in it. A child, thirteen months old, was affected with the disease below the right eye; it had existed for two weeks when he first saw the case, and was apparently caught from her sister. An examination of the contents of the tumours showed them to consist of molluscous bodies, and clear highly refractile epidermic cells. A vertical section through one of the growths showed the same molluscous bodies in the centre, with vacuolation in some of the cells, hyperactivity of gland tissue, and abortive attempt at hypertrophy of gland elements. He considered these tumours glandular in origin, but developed from abortive rather than normal glands. They are always found where sebaceous glands

Digitized by Google

abound; the molluscous bodies are not seen outside the tumour; in structure, too, they are just like glands with the exception of the molluscous bodies, and all three layers of the epidermis can be seen in them. He thought they were most often met with in patients showing other signs of perverted nutrition.—Dr. THIN had advanced the view that these growths were glandular in nature, but arising independently of glands, at the Medico-Chirurgical Society, and was surprised Mr. Startin had spoken of it as if it were original with him. He did not, however, think the view of much value.—Dr. PYE-SMITH would be glad to learn what view the President held of these growths. Was it to be supposed that the tumours are all of sebaceous origin, for he had thought that there were two separate affections included in the term molluscum contagiosum? The first consisted of the glands distended with their own secretion as a result of obstruction of the ducts, while in the second there was a distinct new growth of glandular tissue without any evidence of retained secretion, the columnar cells having undergone molluscous degeneration. There were facts connected with treatment which also bore out this view.—The PRESIDENT remarked that the Germans, and lately Dr. Sangster in a very able paper, had taught that these growths originated from the rete Malpighii quite independently of pre-existing gland tissues. His own view was that they most probably always originated in the same way, for the cases were so closely alike, and he thought there was much to be said in favour of their originating from inactive abortive sebaceous glands. Dr. Sangster, who most strenuously denies this connexion with glands, thinks that the central opening in the growths is the aperture of a hair-follicle, and he thought that if so there was strong presumption in favour of their arising from the neighbouring sebaceous glands. Their close resemblance to glands in intimate structure was strong presumptive evidence of their origin from that source.—Dr. TAYLOR could not recognise the two forms of disease described by Dr. Pye-Smith as both molluscum; he thought most dermatologists would consider the first as sebaceous cysts, and only the second as really molluscum. He did not think the fact of a central orifice was of value in showing their origin from a gland, as he had seen as many as three, and even he thought four, orifices on one small tumour, and he had a microscopical specimen showing three openings, each communicating with its separate acinus, but apparently not separate follicles. The sebaceous glands were originally developed by an infolding of the rete Malpighii, and it was not difficult to imagine a similar process occurring in later life, and leading to the formation of these tumours.—Dr. PYE-SMITH had purposely avoided speaking of the origin of the growths; he was inclined to think both forms grew from pre-existing glands.—The PRESIDENT asked Dr. Pye-Smith whether he had ever seen the two forms he had mentioned occurring on the same patient.—Dr. PYE-SMITH had not seen them. He thought the yellow very contagious nodules often found on the scrotum the most typical example of one variety, and so-called molluscum verucosum of the other.—Mr. STARTIN stated that his view differed from Dr. Thin's, for he believed the growth began in an abortive inactive gland, while Dr. Thin held that it sprang from the rete Malpighii. In many cases he had been unable to find an opening in any part of the little tumours.

Dr. THIN showed photographs, illustrative of elephantiasis, for Dr. Henderson of Shanghai. One group showed the disease existing at the same time in three generations, the grandfather, son, and grandson. Other photographs illustrated the effects of treatment by the elastic bandage. The effect of pressure was to greatly modify the disease, but not to remove it. A photograph showed a complete and permanent cure in a man who had had the disease in both legs. In one leg the limb had become so painful and useless that it was amputated at the thigh through diseased tissue. The result was that the disease disappeared both from the stump of the amputated limb and from the other leg. This effect, Dr. Thin suggested, was due to diminished blood-pressure in the vascular system, consequent on the effect of the operation. Dr. Thin further showed sections and drawings illustrative of the minute anatomy of elephantiasis, the tissue examined being taken from a specimen of elephantiasis of the prepuce recently shown to the Society by the President. The structure was that of an immature fibrous tissue. The cells were distinguished by an unbroken contour and a single nucleus, there being nothing resembling a cell process, nor any appearance suggestive of cell division. They varied in size from that of a lymph corpuscle to the fully-developed cell, which was a typical, flat, endothelial cell of some size. The smaller cells were indistinguishable from lymph-corpuscles, and all gradations of growth to the larger forms were observed. The cells were in all stages distinct from the fibrous tissue, although they were found closely applied to the incompletely-formed bundles. The stellate cells, with dividing nuclei and appearances of proliferation, described by Rindfleisch and Hebra and Kaposi, were not found, Dr. Thin believing that such appearances were produced by unsuccessful hardening. The substantia propria of the tissue had not advanced to the stage of fully-formed bundles. Large masses of involuntary muscle were found distributed through the tissue. In the tissue, near the bloodvessels, the cells were found at places in layers, like endothelial layers. Dr. Thin compared the cells found in elephantiasis with those of normal fibrous tissue, and showed that they agreed in form with the connective-tissue cell, as it had been described by Key and Retzius, and by himself—namely, as an even-contoured, flat endothelium, without processes. The connective-tissue corpuscle of Virchow and Stricker he believed to be formed by the presence of the nucleus of an endothelial cell in the interstices of the tissue, that of Waldeyer and Ranvier by the endothelial cell, with more or less membranous substance adherent to the cell, although some of the cells figured by Ranvier were perfect endothelial cells.—Dr. CAVAFY thought the subject of the shape of the connective-tissue corpuscles of considerable interest. If Virchow's branched cells were really spaces, there was no doubt that in mucous membrane and in cornea the cells were branched. If flat cells were folded or pinched by bundles of fibrous tissue, they would exhibit the winged appearance observed by Ranvier. He regarded all connective tissue as a form of lymphatic tissue. All interfibrillar spaces are lined by flat endothelial cells, and where these cells are found abundant we have to do with an hypertrophy of these lymphatic spaces. Dr. Thin's flat cells were closely allied to endothelium. If the lymphatics were greatly hypertrophied in elephantiasis we should expect a development of muscular fibres in their walls. Had Dr. Thin found the plain muscle thus arranged.—The PRESIDENT observed that Sir J. Fayrer, on seeing the specimen when recent, had informed him that he would be sure to find a large amount of muscular tissue in it.—Dr. CAVAFY asked Dr. Thin if he had employed nitrate of silver as a staining agent in any of his preparations.—Dr. THIN, in reply, said that he did not believe that all the forms alluded to by Dr. Cavafy were found in connective tissue. The one form—the flat endothelium—was the cell; the others were compounds of the cell and other elements. The so-called branched cells of the cornea were not cells at all, but were simply spaces in the same sense as the connective-tissue corpuscles, described by Virchow in a transverse section of tendon, were spaces. He had preparations of the cornea, showing the existence in its substance of complete endothelial layers. In one, a mouse's cornea, he could focus three separate layers at different depths, and in addition there was on the anterior surface of the same cornea from which the epithelium had been removed, a complete delicate endothelium—the sub-epithelial endothelium which had been described in the intestine. In regard to the lymph-canalicular system, he thought the term an unhappy one and conducive of confusion. There were no canals in the sense of walled tubes, and there was not evidence to show that these spaces in the interstices of the tissues are in direct continuity with the lymphatic capillaries, which, as far as we yet know, formed a closed system of vessels in the same sense in which the blood-vessels form a closed system.

Mr. WALSHAM exhibited a Horny Growth, removed by his friend Dr. Marshall from the lower eyelid of an old lady aged eighty-seven. It had originated from a small wart or sebaceous cyst, and had been only two months growing. He brought it forward on account of its exceedingly rapid growth, and because there was no description of the microscopical characters of these growths to be found in the Transactions of the Society. He found the growth to be composed entirely of epidermic cells arranged in columns, which, when cut transversely, showed a concentric arrangement simulating "nests." He had been unable to determine exactly the origin of the growth, but thought it had sprung from a wart.

Mr. GODLEE showed drawings and described a case of

Digitized by Google

Melanosis of the Finger. The girl in whom it occurred was nine years of age, under Mr. C. Heath's care, to whom he was indebted for the specimen. Four years ago the last joint of one finger was noticed to be swollen, and a year later a black spot, the size of a pin's head, was seen in it. This grew a very little, and two years later several other similar very small spots appeared close round it. Mr. Heath amputated the finger, and Mr. Godlee expected to find the growths Melanotic Sarcomata, but he found that the black colouration was only on the epidermis. There was a trabecular arrangement of the deeper epidermis, and the spaces which became more flattened towards the surface contained a dark-red material which was probably altered blood, for on tearing it out he had been able to see blood-corpuscles and altered epidermic cells. The deeper epidermic cells contained brown pigment and oily matter. He had never met with a similar growth, and was at a loss to know in what category of new growths to place it.

Dr. BARLOW showed a Larynx removed from a child eleven months old, the subject of congenital syphilis. When five months old the voice was noticed to be rather weak and hoarse, especially when she cried; there was also a hoarse cough, but no sign of laryngeal dyspnœa. These symptoms varied a good deal, at times passing away entirely and relapsing, probably from catarrh. The child eventually died suddenly after three or four days' illness, apparently connected with the larynx. At the post-mortem examination there was found to be some œdema of the aryteno-epiglottidean folds, very slight erosion of the mucous membrane above and below the vocal cords, and in the ventricles, and some very scanty, thin, and closely-adherent laminæ of false membrane. The cause of death appeared to be the supervention of membranous inflammation upon a chronic laryngitis. He was induced to bring the case forward because Dr. Sémon had recently stated that disease of the larynx in congenital syphilis was very rare. In his experience he had found it of quite common occurrence that syphilitic children, when first brought for treatment with snuffles, thrush, and so on, had also a hoarse, weak voice; but as this rapidly improved under mercurial treatment but little attention was paid to it. In several cases he had noticed that after apparent recovery any fresh catarrh at once affected the larynx, as if a subacute condition were left, which was prone to take on acute change. His colleague, Dr. Warner, had shown him a case of true warty growths in a syphilitic child.—Dr. ALLEN STURGE showed the Larynx of a boy two years and a half old, who came to him suffering from intense inspiratory and expiratory dyspnœa, stridor, and cyanosis; the voice was reduced to a harsh whisper. He had evident signs of congenital syphilis inherited from his father, who had laryngitis severely during the second stage of the disease. The boy improved under treatment by mercurial inunction, but died suddenly while being brought to the hospital. The mucous membrane of the left half of the glottis was much swollen quite down to the rima glottidis; there had been extensive ulceration, which had destroyed both the true and false vocal cords, particularly on the left side, and by cicatrisation had left symmetrical deep fissures and commencing stenosis of the upper part of the trachea.—Dr. LEES was able to confirm Dr. Barlow's statement as to the frequency of affections of the larynx in the course of congenital syphilis. He remembered three cases in which the affection was evidently severe: in one he had been able to see that the epiglottis was thickened and ulcerated; another case had been admitted to the hospital three or four times with urgent dyspnœa, for which it was feared tracheotomy would be required, but the symptoms were relieved each time by mercurials; any catarrh brought them back. This child's sister suffered in the same way till she was two years old, when she died from measles.—Dr. SÉMON had been misunderstood by Dr. Barlow, for he had only stated that in congenital syphilis deeper lesions were rare; superficial catarrh was, no doubt, common enough. Not only were the records of the deep lesions very few, but it was a noteworthy fact that in cases of congenital syphilis with signs of destruction of the nose or palate, only very few examples of destructive disease of the larynx had been found, he himself had never seen any.—Dr. BARLOW mentioned that Dr. Bumstead had observed six cases of very deep ulceration. On the invitation of the President, Dr. John Mackenzie (America), who had specially studied this question, stated that in all he had collected 78 or 80 cases of marked congenital syphilitic disease of the larynx, which he hoped shortly to publish. He thought the affection was as common in congenital as in acquired syphilis; twenty years ago examples of the latter were looked upon as pathological curiosities, as those of the former are now. Many cases were overlooked from neglecting to use the laryngoscope, and because they fell under the notice of the general practitioner rather than the throat specialist.

Mr. ALBAN DORAN and Dr. VINCENT HARRIS showed several microscopical specimens of a Spinal Cord from a fatal case of Tetanus occurring after Ovariotomy, in which the disease had apparently arisen from a cold draught. The tetanic symptoms were well marked, and caused death from asphyxia. The stump of the pedicle was found to be in every way healthy. After careful examination they had failed to find disintegration of the grey cornua described by Lockhart-Clarke, but they had found one or two of the isolated transparent unstained patches described by Dickinson, Coates, and others. These patches were also seen in another cord from a case of tetanus that they had examined. In addition, they had noted proliferation of the small neuroglia nuclei beneath the epithelium of the central canal in the lumbar region; in the cervical region a band of exudation was seen passing quite across this canal, and there were evident signs of exudation in the cervico-dorsal region. They had not found a shrinking of the stellate cells of the grey matter.

The following card specimens were exhibited:—1. Recent Division of Tendo Achillis; by Mr. S. G. Shattock. 2. Calcareous Tumour in Peritoneal Cavity; by Mr. Eve. 3. Specimen of Excision of Knee twelve years ago by Sir W. Fergusson; by Dr. Ledlard.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Nutritive Enemata in Gastric Disease.—Arsenic in Skin Diseases.

AT the meeting of this Society on the 5th inst.—Mr. F. J. Gant, President, in the chair—a paper was read by Dr. THEODORE WILLIAMS upon two cases of Gastric Disease treated successfully by nutritive injections. The first was that of a widow aged twenty-eight, cook by occupation, suffering from symptoms of ulcer of the stomach of some months' standing—hæmatemesis, pain after swallowing food and even cold water, and persistent vomiting. She was extremely anæmic, and had a well-defined area of tenderness on deep pressure in the left hypochondrium. The amount of blood vomited had never been large, recently it was in the form of clots. Various drugs were tried during her attendance as an out-patient at the Brompton Hospital, and a liquid diet enjoined; but the symptoms persisting, she was admitted into the hospital, kept in bed, and fed only by enemata of beef-tea, eggs, and brandy, given twice daily. In the course of sixteen days the vomiting, pain, and localised tenderness disappeared, and she was allowed some solid food by the mouth. This, however, causing symptoms of indigestion, a return was made to the injection treatment for two days. She was discharged cured three weeks later. The second was a case of hysterical vomiting in a young woman aged twenty-two, suffering from chronic phthisis. Here vomiting after food came on and persisted in spite of various alterations in diet and the use of different drugs. Nutrient injections without stimulant were used for eleven days, and then gradually omitted, and in this case also a return to this mode of feeding was rendered necessary for a short time before the case was completed. Dr. Williams urged the advantages of physiological rest in the treatment of gastric affections, as of diseases of other organs; especially as the rectum proves in many cases quite sufficient to flourish the body temporarily.—Dr. DAY remarked upon the difficulty of diagnosis in some cases of persistent vomiting. He mentioned several in which he had obtained good results from the use of nutritive enemata, and considered this treatment especially valuable in the obstinate vomiting of ovarian disease. He recommended that the injection should be small in quantity, consisting of a tablespoonful of port wine, two tablespoonfuls of beef-tea, with five drops of laudanum if required.—Dr. DE H. HALL advocated the use of enemata not exceeding six or eight ounces, combined with pepsine and dilute hydrochloric acid. He advised the use of such injections in advanced laryngeal disease, and mentioned a

Digitized by Google

case of syphilitic disease of the larynx with almost complete stenosis, recently under his care at the Westminster Hospital. When admitted, the patient was extremely emaciated, having been unable to swallow for some time. Iodide of potassium in large doses, ice to suck and nutritive enemata, were ordered, and in a fortnight of this treatment the patient had gained weight, and was able to breathe freely and swallow well. He suggested similar treatment in the advanced stages of laryngeal disease.—Dr. ROUTH pointed out that pain in the left side was frequent in anæmic women, and in these cases the hæmorrhage came from the liver. In one case he diagnosed gastric ulcer from the severe local pain produced by the interrupted current at one spot in the epigastrium. He recommended the use of raw beef-juice every four hours in quantities varying from four to ten ounces, and advised the use of water enemata on alternate days for the purpose of cleaning out the bowel. The white of egg was a good addition; and wine was preferable to brandy.—Dr. DEWAR found the alkaline treatment, with the use of Carlsbad salts, most efficient in gastric ulcer.—Dr. STEVENS mentioned a case where the use of setons had succeeded in the cure of obstinate vomiting.—Dr. ROGERS had tried moxa in these cases with good results.—Dr. FOTHERGILL pointed out the difficulty in diagnosing actual disease of the stomach from reflex disorders due to pelvic irritation. The latter were not uncommon in young females, who complained, in addition to the gastric symptoms, of headache and a feeling of heat in the vagina. He reminded the Society of Dr. W. Robert's method, and stated that he himself had not found it necessary to resort to nutritive enemata for the cure of gastric ulcer.—Dr. GILBART SMITH had at present under his care at the London Hospital a young unmarried woman, who for twelve months had suffered from obstinate vomiting and gastric pain. The usual remedies having failed, a vaginal examination revealed ulceration of the cervix uteri. This was treated in the ordinary way, and the vomiting ceased. Another similar case, with a like result, was still under his care.—Dr. WILLIAMS, in reply, thought that two injections per diem of large quantities were better than small ones given more frequently. He had used this plan of treatment in laryngeal phthisis with great benefit. The use of blisters, moxa, and setons no doubt did good, but they were less efficacious than the treatment he advocated.

Mr. MALCOLM MORRIS read a paper on the "History and Therapeutical Value of Arsenic in Skin Diseases." It was first brought before the profession by Dr. Girdlestone, of Yarmouth, in 1806, and was at once recognised as a valuable remedy in England. Biett introduced it from the English hospitals to that of St. Louis, in Paris, and, following him, the French physicians, especially Cazenave, have been among the first to advocate its use and examine its action. In Germany, however, it has not been so well received, and even at the present time Hebra uses it but slightly. Among English physicians Hunt is the most representative of those who used it very largely and in every disease, and Erasmus Wilson, who believes it to be a valuable remedy, but not to the same extent. Its physiological effects have been examined by Claude Bernard, Lolliot, Sée, and Dr. Binger. They were described according to the action of arsenic on nutrition, respiration, circulation, and the nervous system, and its elimination by the skin, mucous membranes, liver, and kidneys. The increase of appetite is due rather to diminished oxidation than to any direct action on the intestinal mucous membrane. This diminished oxidation is caused by the fact that arsenic has the power, to a great extent, of taking the place of oxygen in the coloured blood corpuscles, and so prevents the blood from receiving its usual amount of oxygen in the lungs. Its action on respiration is also due to its action on the blood—for diminished oxidation means greater freedom of the respiratory movements, and decrease of oxygen in the blood means a greater stimulation of the respiratory centre. Its action on the circulation and the nervous system is more obscure, but in the former there is a marked fall in the blood pressure. That arsenic is eliminated by the liver, kidneys, and mucous membranes is proved by its discovery in the bile and urine, and by its causing bronchitis, conjunctivitis, and diarrhœa. That it is eliminated by the skin has also been proved by its discovery in the serum of a blister and in the sweat; and its special action in large doses on the epidermic cells has been examined by Miss Nunn and Dr. Ringer. Psoriasis is the disease of all others in which arsenic has been most universally used, and its action in many cases is undoubted, though not in all. The author believes this due to the action it exerts on the blood by diminishing not only the oxidation in the tissues, but by absolutely diminishing the number of coloured corpuscles. He had also used it with advantage in lichen planus, pemphigus, and chronic urticaria; but it must not be thought by any means a universal cure for all skin diseases. As some individuals have an intolerance of arsenic, various preparations should be tried before it is abandoned, and it is sometimes useful to combine it with other drugs, even iron. It should always be taken during or after food; should never be pushed to produce the slightest constitutional symptom, and should be continued, to prevent relapses, for a length of time after all traces of the disease have disappeared.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

AT the meeting on March 17th (W. A. N. Cattlin, F.R.C.S., President, in the chair) Mr. FRANCIS FOX read a paper on "Irregularities of the Teeth, and their Surgical Treatment." The early decay of teeth which marks the present generation is due, the author thought, to mal-nutrition occurring in the earlier periods of life. At about seven months after birth a process of absorption is set up in the walls of the crypt and parts superimposed, and by this process the crowns of the temporary teeth become visible above the surface of the gums. When the crowns of the teeth have erupted this absorptive action for a time ceases, and a renewal of the developmental process ensues, by which the alveoli are built up around the fangs of the teeth. At about four years of age the temporary dentition is perfected, and soon after this perfection is reached absorption again sets in, commencing now in the fangs of the teeth, and these, together with their alveolar processes, are gradually removed, their permanent successors replacing them by a similar process of absorption of crypt and development of alveolar structures. The important point to bear in mind is the fact that the alveolar portion of the jaws is developed with each dentition, so that a previous alveolar structure can have little to do with the position of the succeeding teeth, except as it may present an obstacle to their onward progress in consequence of its non-absorption. As to the development of the jaw bones, Mr. Fox remarked that these bones consist of two portions, (1) an alveolar structure, developed with the temporary teeth, absorbed with them, and again redeveloped with the permanent teeth, and (2) a basal portion. This base is more prominently marked in the lower jaw, in which the inferior dental canal very emphatically indicates the junction between the two portions of the bone. The base of the jaw when once formed remains in pretty much the same condition throughout life, except in advanced old age when the muscles of mastication are no longer in full use, and then in a slight degree it becomes wasted. In the superior maxillæ at birth the alveolar processes descend but little below the level of the palatal plates, and the anterior and posterior parts are but little developed. As age advances the alveoli lengthen, the tuberosities increase in size, and an active development of bone takes place in these situations. The tuberosities are to the upper maxillæ what the coronoid processes are to the lower jaw. From these points the alveolar line is lengthened. In the lower jaw an alteration in the position of its articular surfaces and ascending rami, together with an absorption of the coronoid processes, accompanies the development of the posterior permanent teeth. The jaw elongates by additions to its posterior cornua. The capacity of the jaws in childhood is nearly equal to the anterior portions of the adult bones; for the ten anterior teeth of the permanent set in each jaw replace the temporary, and occupy the same position as these, so that this part of the jaw in adult life is pretty much the same as in childhood. If contracted then it will remain so throughout life, and no subsequent development in the posterior regions will tend to expand it. The replacement of the temporary teeth by their successors is effected by a purely physiological process, and is absolutely independent of pressure. There seems to be a physiological

Digitized by Google

law by which the cells composing the absorbent papilla in the neighbourhood of a developing tissue have the power of absorbing a mature structure. That pressure has nothing to do with the process may be proved by the fact, that in cases in which the shedding of the first teeth has taken place prematurely, a layer of bone has often been observed to intervene between the crown of the advancing tooth and the base of the socket of its predecessor. At the time when the temporary teeth are about to be shed, in the well-developed jaw a decided separation between contiguous teeth is noticeable: and this circumstance is a fair indication of a future regularity in the succeeding dentition, and a proof that this portion of the jaw has already been prepared to receive the larger permanent teeth. If the process of absorption continues uninterruptedly, the fangs of the temporary teeth will be gradually removed, leaving little more than the shells of the crowns, which readily drop from the gum as their successors are in turn ready to occupy their places. But should any arrest in this process occur (and such is far from an uncommon circumstance), these temporarary organs are liable to offer very considerable obstacles to the regular advance of their permanent successors. The causes of irregularity in the position of the teeth may arise during the developmental periods of life, and are then due to a want of proportion in the size of the teeth and jaws, or to a faulty development of the jaw bones; or the displacement may depend upon some accidental circumstances arising subsequently, such as the prolonged retention of the temporary teeth, the presence of supernumerary teeth, the habit of "thumb-sucking," or the undue pressure from an hypertrophied tongue. There is abundant evidence to prove how frequently such deformity depends upon hereditary influences. The conditions of life to which our race has for so many generations been subjected seems to have lessened the necessity for the broad and well-formed jaws which were so characteristic of our ancestors, and for many years the advances in civilisation have been marked by a deterioration in the capacity of our jaw-bones. Mr. Coleman, in some interesting investigations made several years ago, found that the percentage of contracted jaws was immeasurably greater in the children of the well-bred population than in those of less refined cultivation. The prolonged retention of temporary teeth is frequently associated with irregularity in their successors, and is probably often the cause of such irregularity. The presence of supernumerary teeth in the dental arch may prevent the normal members from assuming their proper places; but doubtless a disproportion of size between the teeth and jaws is of all causes of irregularity the most common. This disparity leads to a crowding of the teeth, sometimes to such an extent as to altogether prevent the eruption of some one or more of the dental series, such remaining impacted in the substance of the jaws. Certain injuries in early life may occasion displacement of the teeth, especially in the lower maxilla, such as the contraction of cicatrices about the face and neck. Mr. Salter, in his work on Dental Pathology and Surgery, treats the subject of irregularity of the teeth under two heads—(*a*) simple irregularity in which the misplacement is confined to one jaw, and is independent of the position of the teeth in the opposite jaw; (*b*) compound irregularity, which depends upon the position of the teeth in the opposing jaw. In "simple irregularity"—that is, where the misplacement is confined to one jaw, the crown only of the tooth may be irregularly placed, the apex of the root retaining its normal position; or the entire tooth may be displaced, or faulty in its development. Such irregular teeth are often entirely removed from the dental arch, and may be impacted in the substance of the jaw-bones. In the former condition, when the apex of the root retains its normal position, much good may be effected by judicious treatment, but in the latter case little can be done to remedy the evil, except by the removal of the displaced tooth. As examples of "simple irregularity," we may mention the appearance of the upper canines above the alveolar ridge, or in the palate, owing to insufficient room for them in the dental arch. An early loss of their temporary predecessors, by permitting the first bicuspid and the lateral incisor to approach each other, is not infrequently the immediate cause of this displacement. Sometimes, however, the retention of the temporary canine, or the presence of a supernumerary tooth, will occasion its deformity. An overlapping of the incisors is another form of "simple irregularity," and frequently requires for its treatment a resort to some mechanical appliance in order to obtain regularity in the position of these teeth. Another not uncommon form of irregularity is where an incisor tooth is more or less twisted, sometimes to such a degree that the side of the crown will occupy the position of its anterior surface. A forcible twisting of the tooth into its right position is very generally adopted. Some, however, are averse to this prompt treatment, and suggest the employment of a plate carefully adjusted to the palate, and having certain properly-constructed points of resistance. An unsightly separation of the central incisors in the upper jaw sometimes occurs, and the teeth may be readily drawn together, but have a great tendency to return to their former position. In treating these cases great care should be taken to prevent the ligature from slipping below the edge of the gum—between the necks of the teeth and the gum,—for the irritation set up by such a mishap has been known to cause the death of the tooth. In order to prevent this displacement of the ligature, a small vulcanite plate may be constructed to which the ligature can be attached, and thus prevented from shifting its position. The second form of irregularity of the teeth—that depending upon the position of the teeth in the opposing jaw—is much more complicated. As an example might be cited the "underhung jaw," in which the "bite" is intersecting; some or all of the six front upper teeth being shut behind the corresponding teeth in the lower jaw. This condition, in its extreme extent, arises from an undue development of the lower over the upper jaw, or from a want of development in the superior maxillary bones. It may also arise from a retardation in the eruption of the superior incisors, or by these teeth being pushed inwards by the prolonged occupation of the dental arch by their temporary predecessors. An early treatment of this irregularity is all-important, and should consist in preventing the contact of the opposing teeth. An opposite condition of the lower jaw sometimes occurs, in which the lower incisor teeth bite close up to the palate, so that they press against the necks of the upper teeth, and push them forward. A separation of the teeth in the anterior portions of the jaws has been described, and is occasioned by a congenital malformation of the lower jaw. The early obliquity in the position of the ascending rami is unduly maintained, and there is a want of development in the alveolar portions of the jaws, especially in the regions of the molar teeth. This irregularity may be caused by the contraction of a cicatrix in the throat or neck. The bicuspid teeth are not infrequently misplaced, and, when so, they usually occupy a too inward position. This may arise solely from their having been prevented from assuming their proper position in the dental arch by the prolonged retention of the temporary molars. But usually it is dependent upon a diminished capacity of the jaw, and in the upper jaw is generally associated with a projection of the incisors, and a more or less elevation of the palate constituting the V-shaped jaw, or "rabbit-mouth." This malformation is congenital, but, except in very exaggerated cases, is not very manifest until the posterior permanent teeth are about to be erupted, when the additions to the superior maxilla have been made in the posterior regions. The newly-formed bone, which has been gradually developing, is now found to be placed at an angle with the pre-existing alveolar line. This abnormal development has arisen in order to effect an harmonious arrangement with the other bones of the cranium. The maxillary bones having been imperfectly developed during early childhood, their posterior borders not being sufficiently divergent, the subsequent additions for adult conformation are placed in a wider circle; hence the point of junction between the two parts (the old and the new, so to speak) is marked by an angle of more or less extent. It is usually associated with great delicacy of constitution, and may occur in those of weak mental powers, but is often observed in persons of great intellectual capacity. The treatment of these cases consists in endeavouring to gain increased space in the dental arch, and to diminish the projection of the upper front teeth; but is, as a rule, more or less unsatisfactory. Irregularity in the wisdom teeth is sometimes met with, and may occasion most serious mischief, when extraction is the remedy. Transposition of the teeth is rare, and is usually met with anteriorly; and also inversion, which is still rarer.

A discussion ensued, in which the President, Mr. E. Bartlett, Mr. Gaine, Mr. Parson, and others took part. The President then announced that at the next meeting, on April 21st, Mr. Christopher Heath would read a paper on "Thirty-five Years' History of a Maxillary Tumour."

Reviews and Notices of Books.

A Treatise on Hygiene and Public Health. Edited by ALBERT H. BUCK, M.D., American Editor of "Ziemssen's Cyclopædia of the Practice of Medicine," Instructor in Otology in the College of Physicians and Surgeons of New York. Two vols. large 8vo; pp. 792 and 657. New York: Wm. Wood and Co. London: Sampson Low, Marston, and Co. [FIRST NOTICE.]

IN a prefatory note to this work Dr. Buck tells us that in the preparation of the scheme announcing a translation of "Ziemssen's Cyclopædia of the Practice of Medicine" (to use the title given to the American translation), it was thought advisable to omit the first volume of the series, that which relates to the subject of health. This section of the work, treating the subject almost entirely from a German standpoint, failed to satisfy the materially different requirements which existed in the United States. It was determined, therefore, to substitute for the volume belonging to the original series of the Cyclopædia the present treatise written with special reference to the different characters and conditions of soil, habitations, modes of life, and laws of the United States. This judgment was a sound one, and we owe to it the independent treatise now before us. It would be more accurate to say series of treatises, for such the work really is, and it has the additional interest of being entirely written by American writers. Although written, as already mentioned, with a special view to the public-health requirements, legal and other, of the United States, this in no sense detracts from its general interest. The work makes no pretence of treating in other than the broadest sense of the sanitary laws of the United States. The want of uniformity in such of the various States as have legislated on sanitary matters would forbid this. Moreover, so far as the work deals with different conditions of climate, soil, and habitations and special modes of life, this is mainly in illustration of general principles. Hence the book is only in a very limited sense restricted to the peculiar requirements of the United States, and the statement of the prefatory note is somewhat misleading in this respect. Indeed, we are inclined to think that readers of the book on this side of the Atlantic will be disappointed to find that American experience has contributed so little to the whole. But be this as it may, the work is, in reality, a general treatise on the subjects to which it relates, and it is executed with a general uniformity of excellence not always found in works which are the results of the labours of many writers. We may say, indeed, at the outset that the work takes at once a leading place among text-books on hygiene and public health, and that it should become a necessary part of sanitary workers' and sanitary students' libraries. In the latter regard it may be especially noted that subjects are included not usually (if we mistake not, never) found in English text-books; for example, the hygiene of the naval and merchant marine, of coal mines, of metal mines, syphilis, schools, quarantine (both maritime and inland), &c.

We have already said that the work is more accurately described as consisting of a series of treatises, written, as a rule, by different authors. We propose briefly to glance at the several treatises, adding such occasional comments as the limit of our space will admit of.

The first volume opens with an "introduction," and is divided into two parts, relating respectively to "individual hygiene" and to "habitations." The introduction is devoted to a general examination of the causes of disease and the jurisprudence of hygiene, and it is simply necessary to state that it is the work of Dr. John S. Billings to give our readers to know that it is an admirable bit of work. It is especially noteworthy for the clear and thoughtful mode in which some of the most advanced and recondite questions of intimate pathology are treated. The part on individual hygiene is divided into five sections—to wit, infant hygiene (Professor Jacobi, M.D., New York); food and drink (Professor James Tyson, M.D., Pennsylvania); drinking water, and public water supplies (Professor William Ripley Nicholls, Boston, Mass.); physical exercise (Dr. Brayton Hall, New York); and the care of the person (Dr. Arthur van Harlingen, Philadelphia). The several articles are excellent, forming important contributions to our knowledge of the subjects to which they relate. The one on infant hygiene, by Professor Jacobi, is of peculiar value, especially as it concerns infant feeding. Here the author gives us the result of an exceptional experience on the subject which will be novel to most English readers, and which is in the highest degree suggestive. The article on physical exercise is a very able one, and of considerable interest. The other articles rest largely upon data common to Europe and the United States, but their mode of treatment gives a freshness to them which will be highly appreciated here. The second part of the volume, relating to habitations, is divided into three sections—to wit, soil and water (Dr. W. H. Ford, President of the Board of Health, Philadelphia); the atmosphere (Dr. D. F. Lincoln, Boston, Mass.); the general principles of hospital construction (Dr. Francis H. Brown, Boston, Mass.). Dr. Ford's article is a very comprehensive one, including the pollution of the soil in relation to defilement of the air and the drinking-water, and the whole subject of excrement removal. American experience appears to add little to European experience on this important subject, and the impression is left on the mind that the States lag much behind England in readiness of adaptation to particular local exigencies. Or rather it would appear as if the results of English experience on this subject were not as fully apprehended as they might be. Apart, however, from this consideration, the article is of peculiar excellence. Of the articles on the atmosphere and on hospital construction it may be said generally that they are welcome additions to the literature of the subjects.

We reserve our remarks on the second volume for another occasion.

Du Cancroïde des Lèvres et de son Traitement. Par le Dr. ALBERT PEILLON, Chef de Clinique Chirurgicale à la Faculté de Médecine de Lyon. J. B. Baillière et Fils, 1880.

ALTHOUGH we fail to find any new matter in the chapters on the etiology, pathology, symptoms and cause of this common cancerous affection, Dr. Peillon has certainly succeeded in stating well and concisely all the more important facts about the disease. He deals more fully with the subject of treatment, and dismisses as worthless, sometimes harmful, and at the best only palliative, the many external applications that have from time to time been vaunted as specifics for epithelioma. He especially discusses the value of chlorate of potash, and states that its internal administration is certainly useless, but that when applied externally it has in some cases been followed by cure, and should be used where operation is out of the question. He describes clearly and well several useful ways of removing epitheliomata of the lips, and especially describes an operation just introduced by M. Desgrorges of Lyons, and called cheiloplasty. If a large part or the whole of the lower lip be removed by a V-shaped incision, and the flaps brought together along the middle line, it is obvious that the upper lip will be pouted forwards and the buccal orifice much deformed. Desgrorges remedies this by removing a triangular piece from each end of the upper lip; he first widens the orifice by an incision outwards on each side, and the removal of the flaps shorten the lip sufficiently to restore the

Digitized by Google

appearance of the mouth very fairly. We should certainly be inclined to try this method of operating in suitable cases.

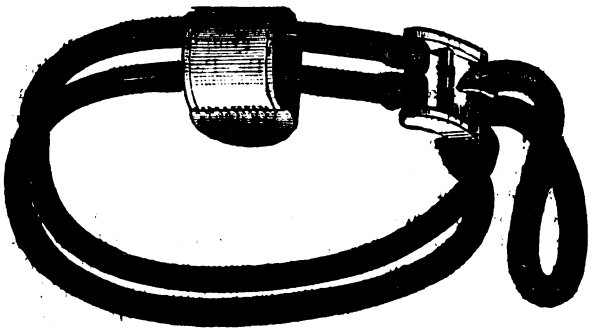
Harvey: La Circulation du Sang; des Mouvements du Cœur chez l'Homme et chez les Animaux. Traduction Française. Par Charles Richet. Paris: G. Masson. 1879.

Englishmen ought to be grateful to M. Richet for being the first to render into his native language the masterpiece of Harvey. It is strange that two centuries and a half have been allowed to elapse before our neighbours should have thought it necessary to have Harvey's writings in a more accessible form than the original Latin version. We congratulate M. Richet on his praiseworthy and successful effort, the value of which is considerably enhanced by the introductory chapter, in which he reviews the theories of the circulation among the ancients and the immediate predecessors of Harvey. He shows how the work of Fabricius, Servetus, and Cæsalpinus had raised the perception of the truth, but it was Harvey, and he alone, who demonstrated it by experiment and formularised a theory which had already been floating in the minds of a few learned men. M. Richet further concisely sums up the directions in which knowledge upon the subject has been advanced since Harvey's day, and he has added to the value of his book by appending some notes upon the mechanism of the circulation interpreted by the light of modern physiology. Altogether the book is worthy of as wide a perusal in England as we hope it may gain in France.

NEW TOURNIQUETS.

We have probably to thank the Ambulance movement for much of the ingenuity that has lately been exhibited in inventing simple apparatus for encountering surgical emergencies. Among the latest results of the movement are two new tourniquets, one on the plan of the india-rubber band, and the other a modification of Petit's well-known instrument.

The india-rubber tourniquet is the invention of Dr. Ward Cousins of Southsea, and is of very simple mechanism and construction. It consists of a movable pad, strong elastic tubing, and a special buckle, and it can be very rapidly adjusted to a limb so as to completely control the circulation. The buckle can also be easily opened and shut, and the



rubber tubing tightened or relaxed *with one hand*. The tourniquet, at once simple and powerful, is suitable to all surgical operations in which such an instrument is required. It will be found particularly serviceable to surgeons in the country, who are liable to be called upon to operate with very limited assistance. In amputating a limb for example, the tourniquet can be opened with the left hand, and a bleeding vessel seized with the forceps by the right; it can then be instantly closed again, and the vessel secured by torsion or ligature. In many accidents attended with bleeding it will be generally useful, inasmuch as it may be applied efficiently even by unskilled persons. We would suggest that a stitch or button in the leather between the two pieces of tubing as they pass over the pad, so as to keep them apart, would add to the safety and utility of the instrument.

The other tourniquet is by Mr. M'Clure, and seems, as already hinted, to be a cheap and simple modification of Petit's instrument. The materials in both are similar, but Mr. M'Clure has substituted for the handle in Petit's tourniquet a large wheel, within which the strong screw works.

The instruments are applied in a similar way, but in the new one a hard wooden pad is attached to the screw, and is powerfully acted upon by a very small action of the wheel. We must, however, point out that in the specimen submitted to us the webbing is too narrow and the pad too small, thereby involving a liability to rolling of the pad on any movement of the limb to which the instrument may be applied.

PUBLIC HEALTH AND THE SOCIETY OF ARTS.

In consequence of the general election, it has been considered advisable to fix the date for the Conference on this subject—which has been held annually by the Society of Arts since 1876—somewhat later than was originally intended, or than has been the case in former years. It will, therefore, be held in the beginning of June. As at the previous Conferences, the Right Hon. James Stansfeld, M.P., late President of the Local Government Board, will be in the chair.

A programme of subjects for discussion has been drawn up by the Executive Committee, and will be submitted to the Conference. The following are the subjects included:—1. The development of Local Government administration, especially by the constitution of County Boards. 2. The extension of the powers of the local authorities of urban and rural sanitary districts. Amendments in the Public Health Act. 3. Sanitary inspection and classification of dwellings. 4. Amendments in the Rivers Pollution Prevention Act. 5. The advisability of strengthening the administrative organisation of the Local Government Board. Local Government Board Administration Areas. 6. Further suggestions by sanitary authorities.

It is announced that the detailed programme will be issued shortly, and that copies can be obtained, when ready, from the Secretary of the Society of Arts, by any person who applies. The programme will also be issued to sanitary authorities throughout the kingdom.

It is not proposed to make any attempt to procure papers which may be read and discussed; but the Committee state that they will be glad to receive any communications containing fresh information, or giving accounts of progress made since the last Conference. Such communications, if approved by the Committee, will be printed and circulated at the Conference, but it is probable that time will not admit of any discussion being taken upon them.

Steevens's Hospital, Dublin.—At the termination of the Winter Session, 1879-80, the following honours were awarded:—Gold Medals: Senior Class, William J. Trotter; Middle Class, William J. Cuthbert; Junior Class, Glascott H. Symes. Honorary Certificates: Messrs. Blackham, Carroll, Clarke, Cruise, Smith, and Wells.

THE LANCET.

LONDON: SATURDAY, APRIL 10, 1880.

THE political crisis through which we are passing will offer a rare and instant opportunity for reform, with which the incoming Premier may illustrate his administrative capacity, sweep from his path many difficulties, and at the outset of his career establish a strong claim to confidence, while he confers on his country a general boon. The weak point in the English system of government as at present constituted, is the isolation of the department which *theoretically* gathers up the reins of local self-government and places them in the hands of the Ministry, but which *practically* not only fails to perform that necessary function, but entangles the ribbons and frets the team. During the last twenty years there has been a fitful and irregular, but, on the whole, continuous and rapid growth of the principle of local self-government, and, strange to say, successive Ministries have been bewildered and embarrassed rather than helped by the circumstance. Instead of looking closely into the phenomenon, accepting it as inevitable, and converting it into a new source of political strength, statesmen have been scared. They have, indeed, made a show of accepting the increased responsibilities thrust upon them, but the action taken has generally appeared to the country, if it has not been in fact, a clumsy piece of centralisation; and while with timid hand they have added to the confusion and trouble at Whitehall, they have been compelled by pressure or moved by fear to throw some new sop or placebo to the local authorities. This position of affairs cannot be much longer tolerated. It is a source of daily increasing dissatisfaction to the country, and the policy of concession to local demands which it necessitates is undignified, and in the end must be ineffectual.

It is easy to cut the Gordian knot of this difficulty, and to render the process of reconstruction facile by the simple and timely precaution of *placing a strong and wise man at the head of the Local Government Board, and making him a member of the Cabinet.* There is no lack of good men at the disposal of the next Premier, whoever he may be. If a statesman in whom the country has confidence—for example, Mr. FORSTER—were appointed President of the Local Government Board, with a seat in the Cabinet, one of the most formidable of difficulties would be removed out of the way of the new Ministry. We have long and importunately insisted on the claims of the country to a Ministry of Public Health. This need would be satisfied if the Minister upon whom it devolves to carry out the provisions of the Public Health Acts were a member of the Cabinet. The immediate effect of such an arrangement would be to make the health interests of the country an integral part of the Ministerial policy. It could not be otherwise. And thus we should gain in fact what the country has been repeatedly promised in a figure of speech, a policy having for its maxim *Sanitas sanitatum omnia est sanitas.* Nor would it be less convenient on general grounds that the member of the Government who is officially in the closest relations with local interests, and who ought therefore to be especially well acquainted with the working details of the economic system, should have a seat in the innermost council of the State, and be able to bring his practical knowledge to bear on the ordinary business of the country.

Domestic considerations play too small a part in the counsels of the nation. It would go far to amend this fault of our traditional policy if the President of the Local Government Board could be admitted to the Cabinet. That Minister, although at present subordinate, is the chief in authority as censor of local improvements throughout England and Wales. He is the judge of appeal in all questions of expediency, as between the executive bodies empowered under the Local Government Acts and the ratepayers. He is at the head of the Poor-law machinery, and commands, in chief, the army of Health-officers. Nothing is wanting but to give the office to a thoroughly good and trusted statesmen, and to include him in the Cabinet. This last point is essential; upon it everything turns. It would be perplexing rather than useful to send an energetic administrator to this department on the old footing, as was done in years past by the two political parties in succession. The work that waits in the office now held by Mr. SCLATER-BOOTH is of a class which can only be done effectively by a Cabinet Minister who would be able to make his influence felt, and to assert the claims of his department, if need be, against the Privy Council itself. The relations into which the Local Government Board must in any great health crisis be thrown with the Privy Council are simply impracticable. In the ordinary discharge of its routine duty even, the friction to which this department is subjected in collision with other nominally, though in no real sense actually, higher branches of the Administration, is destructive to its efficiency. It is a vast Ministry of the Interior, and has claims to a first place in the Government which are unquestionably greater than those of more than one of the departments, which no Prime Minister has yet had the courage to exclude from the Cabinet. What, for example, are the pretensions of the Postmaster-General to a seat at the Council-table, as compared with those of the President of the Local Government Board? The eminent chief of the letter-carrying and telegraphic system might, for any claims his office gives him to a voice in the policy of the country, be a non-political personage. It is a strange anomaly that while this dignitary claims a seat in the Cabinet by right, the head of the local self-government system throughout the country should be an outsider.

We feel it to be a duty to press this matter on the consideration of those who are likely to be at an early date engaged in the construction of a new Government, because the opportunity which exists is very great, and the moment is propitious for the step proposed. The local authorities everywhere are disquieted, many of the Acts which bear directly on local business are working uneasily, and much of the domestic business which presses for attention is of a nature to tax the skill and energy of the new President of the Local Government Board severely. It will, we are convinced, be a blunder to appoint a simply good man, and leave him outside the Cabinet. The sagacity of statesmanship will be better shown by offering the post to a man of proved ability, with a seat in the Cabinet. All that could

Digitized by Google

be necessary at the outset would be to make the appointment. The country would, we are persuaded, hail the procedure as a token of that spirited domestic policy which it, above all things, desires to see inaugurated. Parliament would not grudge the increase of emolument which must be, and, looking to the amount of work now falling on the President of the Local Government Board, ought to be, attached to his office, if it is to be filled by a Cabinet Minister. There might be a saving in some other direction, and it would be easy, if it were not invidious, to point to more than one office of the highest Ministerial rank in which such an economy might be conveniently carried into effect. Enough, however, has been said to place the matter under the consideration of the Ministers of the future, and of public opinion. Our suggestion is made under a strong sense of duty, and because this department of the Government is that with which the great body of medical men are brought into very close relations, and in regard to which they entertain feelings of interest and expectancy. The whole health question may be placed on an entirely new footing by the step we recommend; and it is certainly one which must have a keen interest for the medical profession and the country at large, because it would create a Ministry and give us a Minister of Health—a double boon, which political policy and public expediency both urgently crave.

A RECENT telegram from India describes a fatality which illustrates, only too exactly, the perils of the hypodermic use of morphia. The Italian Consul at Bombay was suffering from a pain in his leg, and called in an Italian doctor, who sent a prescription to a chemist's for a solution of morphia. In this prescription two "grana" of morphia were ordered. The chemist, misled by the word being written at full-length, mistook it for "grammes." An injection was given, which contained, of course, fifteen times the amount of morphia intended. The mistake was, it is said, at once discovered, and remedies applied, but the patient sank rapidly and died the same evening. The accident illustrates, in a striking manner, the danger of error, on which we have often commented, arising from the similarity of the words "grana" and "grammes," whether written at full-length or in abbreviation—a danger which may well make us hesitate in the adoption of the metrical system. Such mistakes, equally facile and equally fatal, will of necessity attend the change of terms, unless a synonym for gramme can be introduced of less dangerous similarity to the word in present use. But the accident illustrates also, in an emphatic manner, a peril which is incidental to, and inseparable from, the use of morphia by hypodermic injection. An over-dose, once administered, is beyond recall. An excessive quantity, given by the mouth, may be removed if, as in this case, the accident is at once discovered. But if injected through the skin, the only resource is the uncertain influence of antidotal agents. We doubt whether the members of our profession are adequately alive to the risks of death which attend this method of using morphia, or whether they are, as a body, aware of the best method of treatment should an accident occur. To other risks attending the subcutaneous use of morphia attention has been of late fully called. By the labours of LEVINSTEIN and others, the danger of habituation, until the daily dose becomes a necessity, is well known. But the comparative rarity with which an injection is followed by dangerous narcotism may easily cause the risk, real and grave as it is, to be underrated. If recognised by all, it is, we think, adequately estimated by few, especially of the younger members of the profession.

Of the reality of the danger, and of its degree, important evidence is afforded by a recent valuable collection of facts, regarding the hypodermic use of morphia, which has been published in New York by Dr. KANE. Our readers may remember that, some years ago, that gentleman published a series of questions on this subject, and the replies which he has received (357 in number) constitute the material of the work to which we refer. It contains information of interest regarding many points connected with the subject, but of incomparably greatest importance are the facts brought together regarding the occurrence of narcotism and death after what we are accustomed to regard as safe doses, the probable causes of these alarming consequences, and the means by which they may be prevented.

In all, thirty-six cases were reported to Dr. KANE, in which death was ascribed to the hypodermic injection, but in only twenty-five of these were the circumstances sufficiently decisive to leave no reasonable doubt of the relation between the supposed cause and effect. "Many of these cases are as well established as it is possible to establish anything of the kind." Moreover we are reminded, and justly, that recorded cases are probably but a small percentage of those in which death results from this cause. "There is a natural delicacy about exposing one's blunders to the world, especially blunders that have compromised the life or caused the death of a human being. Crimes these will be considered, however much the physician may offer in extenuation, or however great a part may have been played by the idiosyncrasy of the patient." In support of this, Dr. KANE adds that he knows of cases other than those reported, where death was attributed to the hypodermic use of morphia, and yet the physicians will not allow the histories, or even the main facts of the cases, to be used anonymously.

An examination of the causes to which the fatal result was due is very instructive. The smallest single dose, which appears to have been, alone, the cause of death, is a quarter of a grain. In one case, however, in which there existed a natural susceptibility to the influence of opium, death apparently resulted from a twelfth of a grain being administered by the skin, after a quarter of a grain had been given by the mouth. In three cases the patients were suffering from delirium tremens, and in one of these, in which the morphia narcosis unmistakably preceded death, only two eighths of a grain had been given. In the vast majority of cases, however, the toxic effect was distinctly due to the repetition of the hypodermic injection, or to its employment after a fair dose of opium had been given by the mouth. In one instance, for an attack of myalgia in a man who was believed to be healthy, though not quite temperate, a quarter of a grain of morphia was given by the mouth, and then a quarter of a grain by the skin. The patient died. In another case one-sixth of a grain was administered by injection to relieve an attack of asthma, and just after it had been given, the administrator learned that half a drachm of laudanum had been given by the

Digitized by Google

mouth before his arrival. This patient also died in spite of treatment.

An important practical point, which is well illustrated by several of the cases, is the fact that tolerance of opium or morphia by the mouth does not prove that it will be tolerated equally well by the skin. Another fact, of equal importance, is that tolerance of morphia by hypodermic injection at one time is no ground for inferring that at another time the same dose would be equally well borne. For instance, a robust farmer had had several attacks of biliary colic, for which he was treated by large doses of morphia, &c., by the mouth. In the last of the series two half-grain doses of morphia were injected, without any ill effect. Six months passed without an attack, and then occurred one of great severity, for which a single injection of one grain was given. But the tolerance which had enabled the two half-grain doses to be so well borne, had disappeared in the interval. Deep narcotism followed, and artificial respiration had to be kept up for six hours. He ultimately recovered.

The data collected illustrate very clearly the known fact that in certain morbid states the use of morphia is peculiarly dangerous. Foremost among these is chronic alcoholism. In a considerable number of cases in which death resulted the patients had been intemperate. This renders its use in delirium tremens peculiarly hazardous, and, as we have said, in three of the fatal cases the remedy was given for this disorder. The existence of chronic Bright's disease also increases the danger, and so also does the existence of disease of the heart or lungs, interfering with circulation and respiration. An important fact which is established by the facts collected, and which is contrary to the opinion sometimes expressed, is that the existence of severe pain does not render large doses better borne. In several cases, as soon as the pain disappeared, the patient passed into a state of imminent danger.

But in a considerable number of the cases in which dangerous symptoms or death occurred, the accident was clearly the result of gross carelessness. Indeed, the inexact manner in which so powerful an agent is employed by some Transatlantic physicians cannot but occasion astonishment, and has, we hope and believe, no parallel in this country. In one case, for instance, a patient, after an operation, received an injection of ten minims of a saturated solution of morphia, and died, deeply narcotised, in two hours. The exact dose of morphia was not known (!), but ten minims of water at 60° F. were found to dissolve six grains and a half. No less than three of the medical men who replied to Dr. KANE'S circular are in the habit of carrying the morphia, for convenience, as a loose powder; and when they have occasion to administer it, they guess at the dose of powder, dissolve it in water, and inject it!

The subject of the treatment of morphia-narcosis is well considered in Dr. KANE'S book, in a chapter which, while presenting nothing that is new, brings together the evidence on the subject in a useful manner. The fact that atropine is capable to some extent of counteracting the influence of morphia must be considered as established beyond dispute; and so also is the fact that it must not be regarded as a simple and complete antagonist. We cannot expect that atropine will do all the work in saving a patient. It may assist, but it needs to be supplemented by the other remedies in common use, and its action may also be assisted by the hypodermic injection of strychnia. But care is necessary to administer only the dose of atropine which is necessary to antagonise the quantity of morphia, and this is 1-25th of a grain of atropine to every grain of morphia. Patients have been killed by atropine given to antagonise morphia. A woman, for instance, was deeply narcotised by half a grain of morphia, and repeated injections of atropia were given to counteract the morphia, until half a grain of atropine had been administered. This was sufficient to antagonise six grains of morphia. The woman died with all the signs of atropine poisoning. Strychnia ought not to be used in larger total quantity than 1-20th of a grain, and a much smaller dose should be first administered. Artificial respiration, electricity, and coffee or caffeine, remedies in common use, may, of course, be necessary in addition.

Another accident which sometimes follows an injection is dangerous syncope. It is often assumed that this is due to the injection of the solution into a vein. It may be so in the cases in which the syncopal symptoms occur with great rapidity, but it is doubtful whether the explanation suffices for all cases. The syncope sometimes occurs only after some minutes, and is apparently due to an unusual susceptibility of the pneumogastric centres for the drug, analogous to that which gives rise to vomiting. Instructive examples of both these forms of syncope are given by Dr. KANE. A fourth of a grain was injected into the arm of a weakly woman for neuralgia. "Within a few seconds the breathing became stertorous, the pulse failed, the lips and countenance became livid, the eyes were set; respiration ceased; the radial and cardiac pulsations were lost; the heart-sounds could not be distinguished. The woman was to all appearances dead." By prompt treatment she was, however, revived. Again, a sixth of a grain was injected into a healthy man for lumbago. In five minutes he was relieved of the pain, but in five minutes more he said, "I think I am going to vomit." "He grew deadly pale, his eyes rolled up in his head so that only the whites were visible, the jaws were clenched, the head was drawn back, and the whole body stiffened, respiration ceasing also." With water to the face, &c., he revived in a few minutes.

Whenever there is reason to think, from the rapidity with which such symptoms come on, that the injection has been directly into a vein, the circulation in the limb should be arrested by a ligature above the place of injection. Moreover, the suggestion is worth consideration, whether in such cases as that reported from Bombay, in which the fact of an overdose is at once discovered, something may not be done by local treatment to arrest absorption. Because symptoms manifest themselves a few minutes after an injection into the subcutaneous cellular tissue, we are not justified in assuming that the whole of the morphia injected is absorbed so rapidly. It seems probable that if a ligature were at once placed on the limb, an incision made through the skin at the seat of the injection, and the part freely washed or even freely cauterised, the amount of morphia absorbed might be reduced to a degree in which its antagonism is possible, and the patient's life might be saved.

THE Indian press publish this week some further details of the reforms and reorganisations proposed by the Simla

Digitized by Google

Army Commission. We have already indicated the principal changes suggested, which embrace the fusion of the Military Medical Service of India with the Army Medical Department, the Civil branch of the Indian Service remaining as at present a semi-distinct body with military commissions and rank, liable to be retransferred to military employ, and acting in times of emergency as a medical reserve. Sir ASHLEY EDEN'S Committee, however, are not content with these proposals, but go still further in their proposals, and would abolish the Royal Service altogether, as far as India is concerned, establishing instead of the present systems a "Local Medical Corps for India." This is to take over the whole medical work, civil and military, of the Empire. The mode of entry into this local service is to be through the British Medical Department, in which all officers must first serve for two years. This notion, we presume, is based on the Indian Staff Corps, which is officered by candidates and volunteers from Queen's regiments of two years' standing. They further suggest that fifty young British medical officers should always be kept in the country to see how the climate and work suit them, and from these, vacancies in the "Local Medical Corps" would be filled. They estimate a saving to the Indian Exchequer of Rs. 2,547,600 annually. As we understand the Committee negative the idea of a local Indian Army (European), we are at a loss to see why they should make an exception for the Medical Department of the Army. The information, however, at present furnished to the Indian Press is so meagre, that we must await fuller and possibly more accurate knowledge before pronouncing a formal judgment on a scheme which may be sweeping and wholesale in its reductions.

The details now furnished modify considerably the statements previously published, and show that the indignation which has been excited on the subject of the proposed changes has been, to some extent at least, uncalled for. It would appear that when the separation is effected between the civil and military services, the loss of the Surgeon-General by the Indian Services in each of the Presidencies, which has been the subject of so many severe comments, will be made up by the creation of a Surgeon-General for the administration of the civil service in each province, in addition to the Sanitary Commissioners and their present staff of medical officers. The Commission propose that, after these officers have been removed from the military branch of the Indian Medical Service, it shall—as previously suggested—be amalgamated with the Army Medical Service, the two forming one list from which the promotions to the administrative ranks shall be made. So that, if this scheme be carried out, the officers of the Army Medical Department will be the losers, for while they will obtain none of the new prizes secured for the civil branch, they will have to share with the military branch the appointments which have heretofore been their portion.

So far as the proposed remedies are known, they seem likely to prove injurious to the Army Medical Department, by abolishing many of their lucrative appointments in India. It should, however, be remembered that these are as yet merely recommendations, which must undergo the scrutiny of the authorities at home, and we are greatly mistaken if they will be sanctioned in the form in which they have been put forward. The necessity for an amalgamation of the two medical services is generally admitted, but it must be carried out on principles of even-handed justice. Neither service must be allowed to bear away an undue proportion of the prizes, and if the Indian service is to come in for a share of the rewards in the military branch, at the expense of the British Medical Department, it would only be justice to admit the latter to a fair share of the lucrative civil appointments. It is stated that in lieu of the course at Netley, young medical officers of the Indian Army will have to undergo a short term of training at one of the Presidency General Hospitals. We trust that the military authorities will never sanction an arrangement so injurious to the best interests alike of the medical officer and of the soldier. The Indian authorities may choose to adopt such a course for the Civil Medical Service, but we cannot believe they will be permitted to introduce a system so prejudicial to the Army.

We opine that the suggestion to form a "Local Medical Corps" will never become *au fait accompli*.

MR. W. H. POWER'S official report to the Local Government Board on an outbreak of typhoid on board the reformatory school-ship *Cornwall*, moored off Purfleet in the Thames, has been issued, and proves to be of even greater importance than was anticipated. It records not merely a singularly successful inquiry into the origin and nature of an obscure outbreak of disease, but it is in the highest degree suggestive of certain lines of further clinical and pathological research of the greatest moment. The report, like previous reports of the same writer (notably his report on the relation of the localised outbreak of diphtheria in the north-western districts of the metropolis last year to the distribution of a particular milk-supply), is an example of the sort of etiological inquiry for which the medical department of the Local Government Board has made itself famous, and of which it is difficult to say whether the acumen of the investigator in seizing upon and following out obscure clues, the severity of the reasoning, or the seemingly inexhaustible industry displayed excite most admiration.

Our readers will probably remember that in the fall of last year the Local Government Board had been requested to send one of its medical inspectors to the assistance of the governing body and medical officer of the *Cornwall* in investigating what was believed to be a renewed outbreak of enteric fever among the children on board. Two or three years before the ship had been the scene of a considerable outbreak of that disease, suspected to have been caused by fouling of the water-supply with excremental matter from a patient sick of the malady. This outbreak had at the time been made the subject of an independent inquiry by the late Mr. HARRY LEACH, and at his suggestion many improvements were carried out in the hygienic arrangements of the ship. Some time afterwards Mr. NETTEN RADCLIFFE had been directed by the Local Government Board to make an inquiry as to the health of the boys on the ship, and as to possible detriment thereto from the position in which the vessel was moored with reference to the overflows of the metropolitan sewage into the rivers at Crossness and Barking, several miles above. Mr. RADCLIFFE'S inquiry, although it is stated that

Digitized by Google

he was unable to complete it, appears to have tended generally to confirm the conclusions MR. HARRY LEACH had arrived at, and to have led to the adoption of a better system for recording any sickness which might happen on board. There is no room for wonder then that the occurrence of apparently another considerable outbreak of enteric fever among the boys was a cause of grave uneasiness and serious disappointment to the governing body, and that aid was early sought from the Local Government Board, through the Home Secretary, for assistance in searching for the source of this seemingly inexplicable reappearance of a disease against which all possible precautions had been taken under highly competent advice. Mr. W. H. POWER was directed to give this assistance; and, in Mr. MORTIMER DE BRENT, the medical officer of the ship, he found a very able coadjutor. Mr. DE BRENT had kept careful records of the most marked cases, and temperature readings of many. The substance of these records is given in a memorandum annexed to the report, and, together with a series of temperature charts constructed by Mr. POWER from Mr. DE BRENT'S notes, form a peculiarly valuable part of it. At the outset of the inquiry, and for some little time after it had been in progress, nothing appeared that suggested a doubt to Mr. POWER'S mind that he was not dealing with ordinary enteric fever. Certainly sundry anomalies in the progress of the disease early struck the mind, particularly in reference to its fatality (one case only having proved fatal in forty-three cases)—its unusual duration in some cases, its triviality in others, &c.; but the diarrhœa observed in several of the severer cases, an eruption of rose-spots, and at times free hæmorrhage from the bowels appeared to set the question of the nature of the disease at rest. Moreover, in the fatal case death was preceded by symptoms which seemed to betoken perforation of the bowel. But in endeavouring to elucidate the conditions which could foster or determine enteric fever among the boys, whether collectively or individually, or in groups, all efforts failed until the question of the possible influence of food as a condition was entered upon. Here it was presently ascertained that the recurrence of cases, or rather groups of cases, had a very definite relation to the use, at intervals of weeks, of a particular form of food—namely, salt meat,—and that this salt meat might have been, and certainly was during a part of the period over which the inquiry had to extend, salt pork. The question immediately suggested itself to Mr. POWER'S mind, Could this pork have been trichinised? Following out this new line of thought, it quickly became apparent that the order of occurrence of the cases was readily explicable on this assumption; that it not improbably would furnish a clue to the observed anomalies in the progress of the disease; and that it might be the outbreak was one of trichinosis, and not of enteric fever. Under these circumstances, permission was sought of the Home Secretary, and granted, to exhume the body of the lad who had died, and who had been buried two months before; and an examination of the body disclosed that there were none of the pathological changes indicative of enteric fever, and that there had been no perforation of the intestine; while, on the other hand, trichinæ were found largely in the muscles, particularly in the diaphragm, some fully grown and *one wandering and living*, others in different stages of less development, and considerable numbers of brood trichinæ were discovered beneath the under-surface of the mucous membrane of the intestine. Here, then, was proof that Mr. POWER'S assumption had been the right one. There could be no reasonable question that the lad had died from trichinosis, not from enteric fever; and the inference naturally followed that the supposed outbreak of enteric fever had been an outbreak of trichinosis following most probably upon the consumption of trichinised pork. The whole course of this inquiry, as detailed in the report, is one of the completest examples we are acquainted with of a true scientific method successfully applied in etiological research.

But the important question remains of the meaning of trichinosis thus closely simulating, as was the case in this outbreak, enteric fever. On the clinical importance of this semblance we need hardly dwell. It must be obvious that in future the possibility of a confusion between the two diseases will have to be present to all practitioners. But Mr. POWER opens another and more recondite view of the question, which he justly designated as of "supreme importance." In view of the symptoms exhibited in the fatal cases, and other sufferers on board the *Cornwall*, he suggests possible relations of enteric fever to a muscular parasite which require investigation, and which might require material modification of current views respecting the etiology and pathology of that disease. We may be assured that this suggestion will not be suffered to remain sterile in the Medical Department of the Local Board.

On the practical side, moreover, the report is far from barren. Meat for the numerous boys on board the *Cornwall* is cooked in bulk, and it is apparent that portions of trichinised meat so cooked escaped the full amount of heat requisite for the destruction of the parasite. Here, then, arises the question of the method in which meat should be cooked for large bodies of persons, in order to obviate such a danger. Again, it should be practicable in all large establishments to secure an efficient examination of imported pork (the sort of meat, it is inferred, here in question), in view of possible infection with trichinæ.

An interesting memorandum, by Mr. POWER in conjunction with Dr. ROBERT CORY, on the microscopical examination of the parasite discovered in the fatal case, with illustrations, is appended to the report.

Annotations.

"Ne quid nimis."

HEALTH IN SCHOOLS.

It will be a happy moment for the health interests of humanity when the process of "education" is made to include training with a view to the eradication of inherited disease, the repression of morbid idiosyncrasies, and the scientific—that is, physiological and psychological—culture of such faculties and attributes of the mental and bodily organism as shall conduce to perfect health. One step in this direction will be taken when the professional trainers of youth, and managers of schools generally, are brought to recognise the scope and importance of the work in which they are engaged. At first we must probably be content to struggle for a better hygienic condition of schools and school-houses

Digitized by Google

than at present prevails. Although Russian authorities on this subject think the English school system perfect from a health point of view, and envy us our advanced position, it would be folly to shut our eyes to the fact that there is much in the *régime* of child-life which is eminently unsatisfactory both in families and "at school." In respect to the food, the clothing, and the habits of the young much remains to be accomplished before we shall even approximate to a perfect system. Meanwhile, it is, perhaps, in respect to the ventilation of schoolrooms, the length of time spent in study, the method of studying, the posture of body long maintained, and the management of light, with the consequent strain on the eyesight of children and of growing youths of both sexes, improvement is most urgently necessary. There is much to be said on these topics, and with a view to lay a solid basis for some practical remarks on the subject, we venture to call teachers and trainers of the young, and schoolkeepers generally, to supply us with brief statements of the system employed in their several establishments. We shall be prepared to classify these statements, and in due season will give the results of our inquiries, with such comments as the data may suggest. The special points to which we have above alluded, together with details of the system of dietary, discipline, and punishments, should form the staple of the communications we invite. It is not opinion we seek, but facts.

THE ACTION OF ALCOHOL.

AN interesting series of experiments on the physiological action of alcohol in its relation to animal heat, and its influence upon the vaso-motor nervous system, has been carried out at the West Riding Asylum by Dr. Bevan Lewis, who has described the results of his investigation in the current number of the *Journal of Mental Science*. Large doses of alcohol lower the temperature of the body, and as Binz has proved that this action is not through the nervous system, it has been inferred that they check tissue metamorphosis. But this involves the assumption that the escape of heat from the surface is not altered. Parkes and Wollowicz, however, could find no evidence that small doses of alcohol check metabolism, and it would therefore seem that, if the two statements are correct, large doses of alcohol lower temperature by lessening tissue change, small doses do not lessen tissue change, and that the action of small and large doses is not the same. But since body heat is the balance between the heat produced and the heat lost, it is evident that the amount of heat which escapes, under the action of alcohol, is an important element in the problem. It is this which Dr. Lewis has investigated, the experiments having been made upon rabbits. The observations were carried on in each experiment in eight successive periods of a quarter of an hour. The heat formation under normal conditions having been ascertained, observations were made after ninety minims of alcohol had been injected. During the first period the production of heat was not far from the normal, rather below in the second, but during the third period it rose to double the normal; during the next three periods it was not far from the normal. A larger dose of alcohol (120 minims, in a smaller rabbit) had a striking effect. During the first quarter of an hour the heat produced was almost *nil;* during the second and third it was greatly increased, more than double the normal; and during the remaining three periods it was still higher. An observation with 180 minims of alcohol gave similar and more marked results. The production of heat was steadily augmented, until on the fifth interval it rose to about four times the normal. Not only is the effect on heat production greater, but it is more persistent after the large doses of alcohol. Thus the maximum production with 40 minims was reached in half an hour, with 90 minims in three-quarters of an hour, with 120 minims in one hour, and with 180 minims in an hour and a quarter. The earliest indication obtained of the action of small doses of the drug always pointed to a primary check to heat formation, which was, however, scarcely recognisable when larger doses were given, being apparently too brief and quick to be measured.

Observations on the temperature of the body showed, it is needless to say, a fall in temperature in all cases. This was greatest during the first quarter of an hour, but proportioned in degree and also in duration to the dose of alcohol which had been given. Not only is the fall of temperature greatest in the first quarter of an hour, when the production of heat undergoes a sensible diminution, but the fall lessens during subsequent periods, and a marked attempt at the restitution of the normal temperature coincides with the period of maximum heat production. In an earlier series of experiments Dr. Lewis studied the effect of chloral in a similar manner, and found almost the same effect upon the production of heat. The combination of the two leads to an extreme vaso-motor paralysis, which is seen very strikingly when alcoholic stimulants have been administered to patients who have taken twenty or thirty grains of chloral. The conclusion, as regards alcohol, is in direct antagonism to the view that in very large doses it lowers temperature by directly checking tissue metamorphosis. The characteristic action of alcohol is to greatly increase the production of heat, whilst dispersion of the freshly-formed heat is facilitated by peripheral vaso-motor paresis. It is only in very small doses that we get a temporary lowering of heat formation.

LONDON MORTALITY.

THE sanitary condition of the metropolis, judged by its recent mortality statistics, can scarcely be considered satisfactory. During the past six months the rate of mortality among the London population has considerably exceeded that recorded among the slightly larger aggregate population of nineteen of the largest provincial English towns. In the last quarter of 1879 the annual death-rate, which averaged 24·2 in the provincial towns, was equal to 24·9 in London; and in the first quarter of this year the metropolitan death-rate rose to 27·3 per 1000, while in the provincial towns it did not average more than 23·8. This signifies that, in equal numbers living, 115 persons have died in London during the past three months to each hundred dying in the provincial towns. This excessive mortality in London is exceptional; but it is a fact, of which the dwellers in London would do well to weigh the importance, that sanitary progress in London in recent years has not kept pace with that in our large provincial towns. That there was greater need and scope for improvement in other large English towns than in London does not afford an entirely satisfactory explanation of this fact. If we examine the mortality statistics of the past ten years, we find that mortality in the twenty largest towns showed a decline of 4·7 per cent. in the more recent quinquenniad, compared with that in the preceding five years; in London, however, the proportional decline of mortality did not exceed 0·7 per cent. In recent years the excess of mortality due to cold has been proportionately greater in London than in other large towns; it is difficult to ignore this fact as affording evidence of low sanitary condition. The recent marked increase of whooping-cough fatality in London is also noteworthy in connexion with the excessive mortality from all causes. During the past thirteen weeks the weekly deaths from whooping-cough in London ranged between 248 and 112, and amounted to no less than 1956 So great a fatality of whooping-cough has not occurred in London since civil registration was established in 1837; the nearest approach to it occurred in 1878, when an epidemic of this

Digitized by Google

disease was unprecedentedly fatal. These facts call for the earnest attention of the metropolitan sanitary authorities and medical officers of health. It is necessary to guard against a dangerous tendency to fatalism in sanitation, which inclines to the belief that excessive mortality due to cold, and to such epidemic diseases as whooping-cough and measles, is beyond the control of sanitary authorities.

ARMY MEDICAL SCHOOL AT NETLEY.

THE Army Medical School commenced its summer session on the 1st instant. Inspector-General Dr. Maclean, C.B., delivered an eloquent address on the occasion, in which he reviewed the past history of the institution, and showed the essential importance of the studies pursued at it in extending the usefulness of the medical officers and promoting the interests of the public service. The classes have opened with sixty-one candidates for commissions in the different branches of medico-military employment—viz., thirty-five surgeon-probationers for the British Army, twenty-three candidates for her Majesty's Indian Army, and three for the Royal Navy. Two surgeons-major of the Indian Medical Service, and one staff-surgeon R.N., are also named in the lists as going through the courses of instruction. Dr. Maclean in his address acknowledged his regret at seeing the small number of representatives of the naval medical service on the benches before him, but expressed a confident hope that, in spite of certain difficulties there might be on the part of the governing authorities in meeting the expectations of those who were advocating various changes in the terms of naval medical service, a satisfactory solution of them would be found before long. The opening of the session was attended not only by the newly-arrived probationers, but also by the military and medical staffs of all the establishments at Netley.

COLONEL CHAPLIN, M.P., AND MR. SEELY, M.P., ON COMPULSORY VACCINATION.

DEPUTATIONS from the Lincoln branch of the Anti-Compulsory Vaccination League have waited upon Colonel Chaplin, M.P., and Mr. Seely, M.P., to ascertain their views with regard to the law of compulsory vaccination. Both gentlemen expressed themselves very decidedly in favour of retaining the law of compulsion as it stands, but both were willing to promote further inquiry on the subject. Colonel Chaplin attributed much of the ill-feeling existing among many people in the country as to vaccination to carelessness of vaccinators in performing the operation; and Mr. Seely appeared to imply a similar conclusion. Both gentlemen held that the benefits derived from vaccination in the restraint of small-pox outweighed the arguments which had been urged in favour of giving up compulsion; and, in like manner, both gentlemen held that the evils asserted to arise from vaccination were overcome by the benefits accruing from the operation. At any rate, they said they would require other evidence than that tendered by the gentlemen of the deputation to alter their feelings as to the necessity for maintaining compulsory vaccination, but they were prepared to consider additional evidence on the subject, and to further inquiry by Parliament which would be likely to throw additional light on disputed points.

OPHTHALMIC SURGERY AND THE MEDICAL CURRICULUM.

FOR some time past the necessity of ranking ophthalmic surgery among the compulsory subjects in the medical curriculum has been strongly urged; and the various licensing bodies may before long require an almost special knowledge of this branch of surgery from all candidates seeking their diplomas or degrees. About this time last year a memorial, emanating from ophthalmic surgeons in London, was presented to the General Medical Council, drawing attention to the neglect shown to the study of ophthalmology in the ordinary course of medical education; and urging the necessity of making it compulsory upon all medical students to attend a three months' course of practical ophthalmology, as well as a course of not less than twenty lectures on the same subject. A memorial from ophthalmic surgeons was also in last November forwarded to the Council of the Royal College of Surgeons in Ireland, and a reply was received concurring in the views expressed in it as to the great importance of remedying the defect in professional education in the matter of ophthalmic surgery, the chief objection which the Council saw to its introduction being the already overcrowded condition of the curriculum. Owing, however, to the presence in the Council of a gentleman who entered that body principally for the purpose of advocating the proposed measure, the College has lately adopted a resolution requiring all candidates for the diploma in surgery after this year to produce a certificate of attendance upon a three-months' course of clinical instruction in ophthalmic surgery.

THE EFFICIENCY OF THE WATER-TRAP.

A CONTEMPORARY publishes an important experimental investigation by Dr. Neil Carmichael concerning the trap and water-closet system, and their relation to sewage products, gaseous and others. As the result of this investigation Dr. Carmichael came to the conclusion that an efficient water-trap excludes soil-pipe atmosphere to such an extent that what escapes through the water is so little in amount, and so purified by filtration, as to be perfectly harmless. The water-trap, he further concludes, stops entirely the passage of all germs and particles from the air of the soil-pipe, including the specific germs or contagia of disease, which, so far as is known, are particulate. He thus traverses entirely the belief so largely entertained that the water of a trap, however perfect in arrangement, will absorb the air of the soil-pipe until saturated, and then give it off harmfully on the house side. He would rehabilitate the old faith in the sufficiency of the water to insure safety, and he would refer the harm from traps to their imperfect sealing, or to various deteriorations in the structure of the water-closet or soil-pipe which permit direct communication between the air of a house and the air of the soil-pipe. The series of experiments on which Dr. Carmichael has founded these conclusions are exceedingly ingenious, and would certainly appear to justify them, but we doubt whether he has been sufficiently careful in indicating the conditions under which the safety of the water-trap can be secured.

CHILDREN ON THE STAGE.

WE have repeatedly characterised the practice of employing children of tender years on the stage as unwise and unhealthy. The death of a child engaged in the performance of a prominent part in a popular little drama at one of the London theatres, has again attracted attention to the subject. It must not for a moment be forgotten that many of the little creatures who sustain parts in pantomimes and other stage spectacles, are more sufficiently fed and happier by reason of the money they earn; and it is an open question whether they would be better off sitting on the doorsteps of miserable houses, or perhaps lying crouched in corners during some violent family brawls than at the play house.

It is idle to suppose that because a death has occurred it must needs be due to the exposure to which the child was subjected. Nevertheless, it will be well if, in consequence of this painful incident, more care is be-

Digitized by Google

stowed on the health of these children. Again, we say, children are not in their proper place on the stage, and it is to be regretted that public taste sanctions their appearance. The career which this early introduction to theatrical life opens to a child is not one which can be considered desirable in itself, or favourable to happiness or morality. The stage may sometimes be a "great teacher;" and we are not prepared to regard players as a class, as less "respectable" than the rest of the community; but no observant person would desire to see children of either sex enticed into the ranks of what is called "the theatrical profession." However, it is with the health aspect of the question we are principally concerned; and on the score of health we would warmly urge the necessity for some public regulation to control an industry which is in the main perilous, although it may, and doubtless does, embody a grain of economic good.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

ON the 1st instant an election for an examiner in the vacancy caused by the decease of Mr. O'Leary, M.P., took place. The candidates at first numbered eight, but on the day of election five only contested the appointment—viz., Benjamin G. McDowel, H. Gogarty, M. Kilgarriff, G. Foy, and K. Franks. Mr. McDowel, late Professor of Anatomy and Surgery in the University of Dublin, was selected, and as he was obliged to resign his seat on the Council in order to compete for the examinership, a vacancy for a councillor has taken place. For this there are two candidates: Dr. Corley, of the Richmond Hospital, and Mr. Nixon, of the Ledwich School of Medicine. The election has been fixed for the 15th inst., so that the successful candidate will have but a short tenure of office, as the general elections will take place early in June.

UNDUE DISINFECTION.

AN action was heard in the Scarborough County Court on the 23rd ult. against a former surveyor of the Filey Local Board in which damages to the amount of £5 were claimed for wrongful action in disinfecting the plaintiff's house. It appeared that while the defendant held the appointment of surveyor to the Filey Local Board he had entered the plaintiff's house without proper notice and proceeded to disinfect it, by chlorine gas it was said, on account of scarlet fever in the plaintiff's family. One of the family, a child, was ill at the time. The family, including the sick child, had to remove from the house during the disinfection, and several days passed before they were able to occupy it again. Various articles were damaged in the house by the mode of disinfection employed. A verdict was given for the plaintiff for the damages claimed, with costs, and immediate execution was granted.

A NATIVE HOSPITAL CORPS FOR INDIA.

WE are told that the want of a trained and disciplined corps of orderlies for service in our army hospitals in India is much felt, especially in the hospitals now in the field. A scheme for such a native hospital corps was drawn up by a committee, which sat in 1876, and of which the new Surgeon-General in India, Dr. Crawford, was a member. Its report has, however, been pigeon-holed, and the result is that every day during the existing campaign the medical officers find the very greatest difficulty in getting servants to fill up the vacancies caused by deaths or sickness. The pay now offered is very bad, far lower than that given even to the dhoolie-bearers, and as a consequence the servants are very often the refuse of the bazaars. They need uniform, good pay, fair pensions, a certain amount of drill, and it has also been proved over and over again that they should be armed for self-defence while serving in the midst of murderous tribes on the frontier. We hear with surprise that hospital servants in India are not eligible for medals for field service. This certainly seems unfair.

DEATH OF BRIGADE-SURGEON CORBETT, A.M.D.

OUR obituary column last week announced the death, at the Royal Naval Hospital, Haslar, on the 25th ult., of Brigade-Surgeon A. P. M. Corbett, M.D., Army Medical Department. Dr. Corbett entered the army as an assistant-surgeon on the 27th October, 1854, was shortly after gazetted to the 68th Light Infantry, with which regiment he served in the Crimea, and was present at the fall of Sebastopol—medal and clasp and Turkish medal. Dr. Corbett was promoted Surgeon-Major on the 14th May, 1867, and was selected for the appointment of Brigade-Surgeon, under the terms of the new Medical Warrant, being gazetted to this rank only a few weeks ago. His death, which was due to Bright's disease, was very sudden, he having been but a few days on the sick list.

IN his report on the Dispensaries and Charitable Institutions of the North-Western Provinces and Oudh (quoted in the *Indian Medical Gazette*), Dr. Walker shows that the surgical work done in these hospitals is yearly increasing in amount and importance. The number of large operations performed amounted to 6857, against 4711 in 1877. The list includes 29 amputations of the thigh, 46 of the leg, 32 of the arm, 30 of the forearm, 434 large tumours and cancers removed, 835 operations for the removal of stone from the bladder and 3097 for cataract. There were only four cases of lithotrity, all successful. The death-rate in lithotomy was 8·2 per cent., against 7·8 in 1877. The higher rate of mortality is attributed to the lowered health and physique of the population due to fever and privation. The rates for subjects under twenty were below the average, and those for persons above twenty considerably higher.

THE inquiry into the Lower Thames Valley main sewerage scheme drags its slow length along. The sewage farm at Molesey has been officially inspected, and the plan of Colonel Haywood has received favourable testimony from chemical experts, as well as from Mr. Baldwin Latham. Cross influences, however, seem to be at work. The latest phase in the matter appears to be an application for a provisional order not only to establish a sewage farm at Molesey, but to give the joint Board two years' grace to carry out proper drainage works, and so save penalties threatened by the Conservators for not complying with their order to prevent the sewage going into the Thames. "The latter half of the application," says the *Surrey Advertiser*, "is unopposed, so that in case Colonel Haywood's scheme is rejected, the Board will have to begin *de novo*."

AT a meeting of the lecturers of the Minto House Medical School, held recently, Mr. Geddes was unanimously elected to the vacant Lectureship on Natural History. Mr. Geddes was formerly demonstrator of physiology in University College, London, and more recently of zoology in the University of Aberdeen. We understand that he has just returned from a zoological and palæontological expedition in Mexico, and that he has had considerable experience at the French, German, and Scottish zoological stations.

THE Indian Government have given orders for the construction of a hundred dhoolies, of the pattern designed by Surgeon-Major Hamilton, for service with the army in Afghanistan. This conveyance for the sick and wounded was described at length in our columns on the 23rd of last June, and reports from medical officers serving with the army in the field fully bear out the anticipations expressed as to its simplicity and usefulness.

Digitized by Google

SURG.-GEN. J. FULLARTON BEATSON, C.I.E., the head of the Bengal Medical Department in Calcutta, retires from the service from the 1st April, his term of duty having expired. Under the new orders of the Government of India regarding the medical administration of the Indian Army, the military Surgeon-Generalship will cease to exist, Dr. Crawford, the principal medical officer of the Royal Army, advising Government on all questions concerning the native troops. Dr. Cunningham, of the Bengal Medical Service, remains as Sanitary Commissioner, and will, it is believed, become Civil Surgeon-General, in addition to his other duties, when the new organisation has been finally sanctioned.

WE would call the attention of young surgeons wishing to increase or complete their stock of surgical appliances, to the sale of the cases of instruments belonging to the Stafford House Committee. The instruments, which include several sets of resection apparatus, are in good condition, most of them being quite new.

THE Secretary to the Government of Bengal has addressed a highly complimentary letter to Surgeon-Major S. B. Partridge, on his resignation of the professorship of Surgery in the Calcutta Medical College and the first surgeoncy of the College Hospital.

THE Vice-President, Council, and Secretary of the Royal College of Surgeons in Ireland, on the 1st inst., presented Dr. Mapother, the president, with six silver saltcellars, in the form of cradles, to commemorate the birth of his child during his year of office.

A MEDICAL SOCIETY has been established at Dacca. The members consist of the teachers of the Medical School, the Civil Hospital assistants attached to the Mitford Medical School, the local practitioners and students.

THE Hospital Saturday and Sunday movement appears to have firmly established itself in New York. On Dec. 28th and 29th the amount collected on behalf of the fund was 25,811 dollars.

DR. BANKS has been elected the Representative of the Queen's University in Ireland in the General Medical Council.

DR. LYONS has been returned to represent Dublin in the Imperial Parliament.

HEALTH OF LARGE ENGLISH TOWNS.

THIRTEENTH WEEK OF 1880.

UNDER the influence of recent cold east winds English urban mortality shows a further increase. In twenty of the largest towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5077 births and 3578 deaths were registered last week. The births were 108 below, whereas the deaths exceeded by 303, the average weekly numbers during 1879. The deaths showed a further increase of 420 upon the low numbers returned in recent weeks. The annual death-rate in the twenty towns, which had been equal to 21·4 and 21·9 in the two preceding weeks, further rose to 24·9 last week. During thirteen weeks ending last Saturday the death-rate in these towns averaged 25·5 per thousand, against 24·2, 25·2, and 27·5 in the corresponding periods of the three years 1877–8–9. The lowest death-rates in the twenty towns last week were 14·4 in Portsmouth, 18·5 in Wolverhampton, 19·6 in Bradford, and 20·2 in Sheffield. The rates in the other towns ranged upwards to 29·3 in Hull, 29·5 in Salford, 29·8 in Oldham, 31·3 in Manchester, 34·1 in Plymouth, and 35·5 in Nottingham.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 476 and 424 in the two previous weeks, rose to 531 last week; these included 215 from whooping-cough, 119 from scarlet fever, and 107 from measles. Only 28 deaths were referred to fever, principally enteric, of which 5 occurred in Sheffield, and 3 in Salford. The annual death-rate from these seven diseases averaged 3·7 per 1000 in the twenty towns; it was but 0·7 and 0·8 in Wolverhampton and Leeds, but ranged upwards to 7·3 and 11·8 in Salford and Plymouth. Whooping-cough showed the largest proportional fatality in Salford and Manchester; scarlet fever in Sunderland and Nottingham; and measles in Plymouth, Nottingham, Hull, and Oldham. The 21 deaths from diphtheria in the twenty towns included 11 in London, 3 in Liverpool, 2 in Leicester, and 2 in Bradford. Small-pox caused 10 more deaths in London and its suburban districts, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which in the three preceding weeks had declined from 188 to 167, were 172 on Saturday last; 47 new cases of small-pox were admitted to these hospitals during last week, against 25 and 31 in the two previous weeks. The Highgate Small-pox Hospital contained 19 patients on Saturday last.

A considerable proportion of the increase of deaths last week was due to the greater fatality of lung diseases. The deaths referred to diseases of the respiratory organs in London, which had been 315 and 334 in the two preceding weeks, rose to 396 last week, but were 94 below the corrected weekly average; 256 resulted from bronchitis and 92 from pneumonia. The annual death-rate from diseases of this class was equal to 5·6 per 1000 in London last week; in Liverpool the rate from the same diseases was 7·0 per 1000.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hastings.—Mr. Charles Ashenden presents a highly satisfactory account of the sanitary state of health of Hastings during the past year. The death-rate (16·84) was that of a rural rather than an urban district. We note with gratification the good use to which the infectious diseases hospital (sanatorium as it is euphemistically called) of the town is put, and the readiness with which mechanics and small tradesmen availed themselves of it in cases of infectious sickness, also of the sanitary authorities' disinfecting apparatus. Few things will more certainly redound to the popularity of a health-resort among visitors than the knowledge that it is prepared to diminish risks from infection to the lowest point.

Hereford, City and County.—Dr. Vavasour Sandford's annual report for the combined rural and urban sanitary districts under his sanitary supervision shows a heightened mortality from diseases other than infectious and contagious, and "almost a total immunity from this latter class of maladies." This immunity he assigns to the efficient sanitary administration of the districts in regard to current infections; and the greater prevalence of other sorts of sickness, which is to be inferred from the greater mortality from them, he attributes to the sunlessness and unusual humidity of the seasons. Man, in fact, suffered in common with the crops and herds from the exceptionally bad weather which prevailed last year. He draws especial attention to the operation of the Public Health (Water) Act of 1878 in his district, and states that with respect to the "reasonable distance" of a water-supply from a dwelling, his sanitary authorities have laid down the rule that in regard to houses now in occupation, 500 yards shall be regarded as a "reasonable distance," but that in respect to houses built hereafter, 200 yards shall be so regarded. He has some remarks deserving of special attention upon the failure (too common, it would appear, in his district) to provide good water, in connexion with schools, for the use of the children.

Maidstone.—Mr. Matthew A. Adams reports for the past year a birth-rate of 32·9, and a death-rate of 19·5. Maidstone has much to do before she will have relieved herself from the filthy backslums she possesses, and not a few dilapidated and damp dwellings, as well as her offensive privies. But she seems to be moving in the right direc-

Digitized by Google

tion, and her medical officer of health seems hopeful for the future.

Peterborough (Urban).—Dr. Thompson reports a death-rate of 22·4 in 1879, as against 24·1 in 1878. Scarlet fever appears to have been prevalent in the city during a great part of the year. But Peterborough has neither a hospital for infectious diseases nor a disinfecting apparatus!

Thingoe.—Mr. Charles Scott Kilner reports a death-rate of 16·5 per 1000 population in this rural district for the past year, as against 12·5 in 1878, the greater mortality occurring among infants and persons above sixty years of age.

Tottenham.—Dr. Watson refers to the extraordinary growth of this place. From February, 1875, to February, 1880, the Local Board, it appears, have approved of no less than 15,500 (or thereabouts) plans for houses. Nevertheless the death-rate from all causes in 1879 did not exceed 17·6, and there are other indications that the sanitary administration of Tottenham is now being carried out by its Local Board with much efficiency.

THE ROYAL COLLEGE OF SURGEONS.

AT a special meeting of the Council, held on Wednesday last, Mr. John Cooper Forster was unanimously re-elected a member of the Court of Examiners in Surgery. At a quarterly meeting, held on Thursday, the minutes of the preceding ordinary meeting, held March 11th, were confirmed, after a long criticism, by Mr. Simon; the report of the Committee on bye-laws relating to fees being adopted, with some modifications, the most important of which is the retention of the payment of fees by examiners on election. The Collegiate Triennial Prize was awarded to Mr. G. A. Woods, of Southport, for his essay on "The Anatomy and Physiology of the Third, Fourth, and Sixth Nerves."

Correspondence.

"Audi alteram partem."

MR. BADCOCK'S EXPERIMENTS ON THE VARIOLISATION OF KINE.

To the Editor of THE LANCET.

SIR,—Mr. Badcock, of St. James's-street, Brighton, having suffered in his infancy severely, and being much marked with the small-pox, determined upon performing some experiments upon some cows, which he kept, by inoculating them with the matter of the small-pox taken from the human subject. About forty years ago, the late Sir Cordy Burrows gave Mr. Badcock some small-pox ichor, which he had taken from one of his patients; Mr. Badcock inserted this ichor into one of his cows. After the lapse of a week, when it had produced a vesicle upon the cow, a human subject was vaccinated with the lymph thus produced, and the result was the facsimile of the vesicle which Jenner discovered fifty years before. Mr. Badcock employed a photographer, who took from the cow the likeness of the vesicle which he had produced, and then exhibited the photographs to the Brighton Medical Society, thus triumphantly confirming the value of Jenner's discovery, and placing the protective power of the vaccine upon an indisputable basis. The vaccine discovered and the vaccine produced being identical, it is a proof that the vaccine is unalterable, for after passing through the constitutions of 2500 persons during fifty years, it remains precisely the same thing. The fact is, vaccinia is a disease *sui generis*, and, like the small-pox, measles, and scarlet fever, incapable of admixture with any other disease. If you sow a radish seed you cannot produce a cucumber. If you sow a bean you will not produce a carrot. As well might it be said, that you can produce vaccinia by syphilis, as that you can produce syphilis by vaccine. This is not my opinion only, but also of all those public vaccinators (and their name is legion) whose opinions I have elicited upon the subject. I accompanied Mr. Badcock to his stall, and saw him take some vaccine from a cow which he had variolated the week before. Being at the time public vaccinator to the Western district of Brighton, I inserted the matter so taken, which Mr. Badcock kindly gave me at the time, into one of the children. I kept up that supply for about twenty years, until I resigned the office, as I preferred the matter so converted to all others. A great objection, and much of the prejudice against vaccination, would, I think, be removed by the most gentle method of vaccinating. I make a few horizontal scratches on the arm, just penetrating the cuticle; then, removing the blood and stretching open the incision, I insert the matter. By this means I have produced excellent vesicles without awakening a child who was asleep. By this method a peculiar mark is left on the arm, which is easily recognisable. Since my retiring from practice in 1870, Dr. Ross informs me two epidemics of small-pox have occurred in Brighton, but that *not one person so marked by me has ever been attacked by the small-pox.* One peculiarity with me is that I always vacciuate both arms, and taking the matter from one arm leave the other untouched, to be absorbed into the constitution, for the better protection of the person vaccinated. All honour, then, to Messrs. Ceely and Badcock, who have thus so satisfactorily solved the problem, till that time inexplicable—namely, Why does vaccination prevent the small-pox? and thus, by placing it as it were into a living alembic, have transmuted the small-pox from a repulsive, disfiguring, blinding, deadly disease into one perfectly harmless, as we have seen in Brighton, even to an infant just born.

I am, Sir, yours respectfully,

D. RICHARDSON, M.R.C.S., L.S.A.

Newhaven, Sussex, March, 1880.

SIR W. JENNER, BART., ON ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—By the last San Francisco mail arrived the numbers of THE LANCET for November containing Sir William Jenner's address on the treatment of enteric fever and Sir Joseph Fayrer's address on assuming office as president of the Epidemiological Society.

I should not presume to question Sir W. Jenner's authority on any point as far as concerns enteric fever, as seen in London, or even in England—although enteric fever in rural districts among paupers differs widely from that seen in London—but a reference to Sir Joseph Fayrer's address shows that on one important point the Indian authorities are at variance with Sir W. Jenner. The latter speaks of it repeatedly as a specific disease, produced, "in the majority of cases at least, by the action of a small portion of the excreta from the bowel of a person suffering from typhoid fever." (THE LANCET, Nov. 15th, 1879, p. 715.) Sir Joseph Fayrer maintains that "a form of fever exactly like European typhoid, except in its etiology, exists in India, and other hot and malarious countries, and that it is due to *climatic causes, not to filth or specific causes.*" (THE LANCET, Nov. 8th, 1879, p. 678.) The italics are mine. Sir William Jenner maintains that he has "never known a case of typhoid fever cut short by any remedial agent that is cured," and that the "natural duration of a well-developed case of typhoid fever is from twenty-eight to thirty days." Sir Joseph quotes from a report of Surgeon-Major A. Clarke a statement that numerous cases entered as enteric were discharged, and at their duty five or six days afterwards, though "rose-spots are invariably present, and in fatal cases the lesions of Peyer's patches are well marked." In other words, the disease is either cut short by treatment, or there are numerous cases of such a mild character that they get well in a few days.

Now, everyone who has seen enteric fever in tropical countries and amongst other than European races, must agree with Sir Joseph Fayrer. The disease is most protean in its character, and unless one is prepared to maintain that in the same house, in the same climate, amongst people living under exactly the same conditions, two or more forms of fever can spring up at the same time, one must admit that the same poison will vary in its effects on different individuals according to their constitutional peculiarities.

I have seen an epidemic of enteric fever breaking out on board an emigrant ship in lat. 41° N., continuing with us after we had rounded the Cape of Good Hope, lat. 34° S., and thence on until after we reached Dunedin, New

Digitized by Google

Zealand, lat. 46° S., with gradually increasing severity. I took careful notes of all the cases, sixty in number, and some of them were cases that would be called febricula at home, lasting only a week; others, commencing in exactly the same way, were cut short by producing profuse diaphoresis, and terminated in a couple of days; while twelve were fatal on board ship, and four more died in quarantine. All the fatal cases presented the characteristic lesions of Peyer's patches. Fever broke out after we had been at sea a month. Surely no one could doubt that all the cases were caused by the same poison, although they differed greatly in the symptoms, duration, and severity of the disease.

As regards treatment, I am rather surprised that Sir W. Jenner says nothing about the unmistakable action of aconite in lessening the frequency of the pulse and lowering temperature in the early stages of the fever. For the last twenty-five years I have been in the habit of giving aconite in the form of Fleming's tincture, three to five minims, every four hours, with this object, and have rarely seen it fail to do good, not only in enteric fever, but in all febrile diseases or acute inflammations. The wet pack is also a most powerful agent, and affords immense relief. I use it with the view of assisting the elimination of the poison by the skin, on the ground that the poison, by producing the rose-spots, shows a tendency to eliminate itself in that way, and if we can encourage this tendency we shall lessen the danger of internal lesions.

Sir W. Jenner does not mention a valuable practical rule for the administration of alcoholic stimulants, which I was taught as a student—namely, to listen daily to the heart, and give stimulants as soon as the first sound begins to flag. I have found in the tropics that good sound Bordeaux wine answers in most cases even better than spirits. Preparations of bark, particularly the liquid extract, are also very useful in the latter stages of the disease.

It may seem presumptuous in an unknown practitioner to venture on criticising a man of Sir W. Jenner's justly-earned reputation; but, after all, a man who has treated enteric fever in London and the rural districts of England, in the wards of the Scutari Hospitals, in the Crimea, in the West Indies, in South America, in Australia, in New Zealand, and in all the climates ranging from 52° N. lat. to 37° S. lat. —among Europeans of almost every nation, negroes, Chinese, East Indians, both Hindoos and Mahometans, and in white and coloured natives of tropical regions—may perhaps be pardoned if, after being engaged in the study and practice of the profession for thirty-two years, he has an opinion of his own—*pace* even Sir William Jenner.

I am, Sir, yours, &c.,

R. H. BAKEWELL, M.D.,

Surgeon Superintendent of the Totara District Hospital, Ross, New Zealand.

Ross, New Zealand, Jan. 24th, 1880.

THE CROTON-OIL TREATMENT OF RINGWORM.

To the Editor of THE LANCET.

SIR,—Having just read Mr. Cottle's instructive paper on the croton-oil treatment of ringworm in THE LANCET of March 27th, in which he refers to my paper on the same subject published in the January numbers, I at once frankly admit that he *published* a treatment by croton oil previous to the appearance of my paper; yet in justice to myself I ought to state that I had neither seen nor heard of Mr. Cottle's paper read before the Dermatological Section of the British Medical Association in August last, that my paper was written at least eighteen months ago, and that I have specially worked out the croton-oil treatment of ringworm for over six years. I did not publish my results till January last, as I wished to thoroughly try the treatment before bringing it under the notice of the profession; and during the last few years I have frequently spoken to many dermatologists about it.

But I fail to see from the report I have now read of Mr. Cottle's former paper, or from his recent one in THE LANCET, that his treatment is quite the same as mine. It appears to me to differ in a most essential point.

Mr. Cottle says that I appear to him to carry my treatment "to an unnecessarily severe extent;" and he advises an application of the oil "to produce a deep pustular rash;" he also thinks it sufficient to set up a pustular rash involving the tissues to the depth of the hair-follicles, and "*that the formation of a subcutaneous abscess is unnecessary;*" and again, "that it is not necessary to produce *a real subcutaneous abscess or kerion*,"—"a copious pustular rash being all that is required."

Now in the first place, as it would appear from the above that I am in the habit of producing an abscess, I must call attention to the fact that *kerion* is not a subcutaneous abscess, and that I have never advised the formation of abscesses or any other such severe treatment. "Kerion," according to Dr. Tilbury Fox, "has the *appearance* of a threatening abscess; the patches are swollen, puffy, raised, red, tender, feeling semi-fluctuant and soft. They are studded over with little openings which are the mouths of the hair-follicles, and from which a muciform or purulent discharge exudes. Some of the hairs fall out, others lie loose in the follicles." This is true kerion—a variety of the disease that may occur under any treatment—the artificial production of which I specially advised in my paper, and not the simple formation of a pustular rash, which, though it is certainly very effectual in curing ordinary chronic ringworm, yet will most certainly fail in the inveterate forms of the disease. The pustular rash is not therefore the essential part of my treatment, but the actual infiltration of the true skin with inflammatory products, causing the hair to become loosened. If this state can be produced the case is practically cured, and the further use of parasiticides is not necessary, as the inflammatory effusion destroys the fungus.

Secondly, I must mention the fact that I only advised this "severe treatment" in those chronic cases that have resisted all ordinary applications, and can most positively affirm, from six years' experience, that the croton-oil rash alone will not cure many of the inveterate forms of the disease. If the case be left alone after one or two applications of the oil, followed by a pustular rash and yellow incrustation, but without the puffy swelling of the part, all may seem well, and the disease may appear to be cured, yet the stumps will crop up again and again. I speak very strongly on this point, as medical men so often make a mistake in thinking a patch well because it *appears* free from stumps. In ordinary private and hospital practice cases are often not seen again because they are considered well, and yet if they were examined after two or four weeks (as boys are, after having had ringworm, in a large school) the diseased stumps would constantly be found to have reappeared.

Mr. Cottle seems to prefer the croton-oil liniment to the pure oil. I always used the former preparation at first, but gave it up four years ago for the oil, as the alcoholic solution is more apt to run beyond the limits of the spot painted with it, and thus to cause pustulation where it is not wanted. This is especially seen when applying the oil to isolated stumps, as described in my paper.

The essential difference, therefore, between Mr. Cottle's treatment and my own is, that while Mr. Cottle seems satisfied with a deep pustular rash, I try by repeated poulticing to produce an *imitation* of true kerion, which is nature's certain cure of the disease. The process I advise I have already fully described in my paper, published in the January numbers of THE LANCET.

In conclusion, I may add that I am only too pleased to find Mr. Cottle has been employing croton oil as a remedy for ringworm, and that my object now is not so much to seek priority as to get the profession to recognise the efficiency of the croton-oil production of kerion as a certain and speedy cure in the most inveterate forms of the disease.

I remain, Sir, yours, &c.,

ALDER SMITH, M.B. Lond., F.R.C.S.,

April 6th, 1880. Resident Medical Officer, Christ's Hospital.

TREATMENT OF RHEUMATISM BY IODIDE OF POTASSIUM AND OPIUM.

To the Editor of THE LANCET.

SIR,—If there is one science which is and ought to be progressive it is the science of medicine, whereas if we agree with Dr. Barton in THE LANCET of Feb. 14th we must remain satisfied with a conservatism which contents itself with that which is unreliable and often inefficient. For I think he will hardly venture to state that the treatment of acute rheumatism by iodide of potassium is so satisfactory in its results as to leave nothing more speedy or effica-

Digitized by Google

cious to be desired. He says, "Why resort to doubtful and dangerous remedies merely because they are new?" But surely if we are not to try new remedies, but to continue those which are old and often utterly inefficient, we shall make no progress at all. From what I have seen in hospital practice of the use of iodide of potassium in the treatment of acute rheumatism, it is of little avail in meeting any of the urgent symptoms, such as pain, effusion into the joints, or high temperature, and Dr. Barton is compelled to supplement it by blisters, Dover's powder, &c.

Anyone who has seen two cases treated, the one with carefully-regulated doses of salicylic acid, where the patient is free from pain and swelling, with an abated temperature, in from twenty-four to thirty-six hours, and the other treated in the old-fashioned and somewhat barbarous plan of blisters, first on one joint, then on another, &c., until the patient suffers almost as much agony from the blisters as from the disease, and where, finally, the disease itself remains almost unabated, only shifting its quarters, and lasting "generally a week or ten days"—anyone who has seen such cases could not fail to say at all events in which case there is the least pain.

I think Dr. Barton is in error in stating that salicylic acid has in any one case been proved to have caused a fatal result, and I demur to his calling it "a doubtful and dangerous remedy." There is no evidence whatever to show that deaths or cardiac complications are more frequent under its use, if not the reverse. I have treated some fifty cases with salicylic acid, combined with the minimum of bicarbonate of soda and ammonia, to effect its solution, and published a letter with a report of a few in THE LANCET, 1877, whilst I made a series of experiments upon guinea-pigs,[1] &c., giving one twenty grains every day for a fortnight, without any ill results, the said animal being alive a year after, and I also gave it doses of ten grains, which, considering the size of the animal, is a very large dose.

Whatever may be the relative merits of the salicylic-acid treatment, and that by other methods, such as the alkaline or iodide of potassium, as regards the frequency of relapses, the chances of cardiac complications—these are only to be determined by an accumulated amount of experience, and revealed by statistics; but I am of opinion, from my own experience, and that of many others, that the former method of treatment is far superior to the other methods in the rapidity with which it lowers the temperature, and relieves the pain, if it does not also shorten the duration of the disease.

Timidity in dosing (which is but natural to those who believe in the dangerous nature of the remedy) is one cause, and the principal one, of the failures which occur in the salicylic treatment. I found that I could detect it in the urine within ten minutes after its administration, and in the blood in less than that time. Considering then its rapid elimination from the system it is useless to give doses of ten or fifteen grains every four or six hours.

In the report of the Boston City Hospital, 1877, as regards the duration of the disease under this treatment, the average time to relief of pain was 1·46 days, complete cessation of pain 2·85 days, the average time the acid was given was 6·22 days, and the stay in the hospital 18 days. The total number of cases, 106. These figures certainly show better results than any yet obtained under any other treatment; at the same time they are much more favourable than Dr. Southey's recently-reported account of fifty cases under the same treatment.

I believe that by the use of a combination of iron and salicylic acid the anæmic condition and debility frequent after the use of the acid alone, or combined with soda, may be avoided, and thus the stay in hospital, apparently so prolonged after the actual cessation of the disease, may be shortened. I have always given it in this form after the first few days, and the result has been most satisfactory.

The form in which I use the acid is as follows:—Salicylic acid, 20 gr.; carbonate of ammonia, 5 gr.; bicarbonate of soda, 5 gr.; water to one ounce; and I afterwards add 5 or 10 minims of tincture of perchloride of iron. I have found this more effectual than the simple salicylate of soda, and less depressing. It is also much more active than salicine.

As far as regards relapsing and subacute rheumatism (and Dr. Barton's remarks would appear to apply to that form rather than to the acute disease), I have found that the salicylate treatment is not so successful, and I prefer to use iodide of potassium or some other drug.

I remain, Sir, yours truly,

ENGLEDUE PRIDEAUX, L.R.C.P. Lond., &c.

Wellington, Somerset, Feb. 17th, 1880.

*** The publication of this letter has been unavoidably delayed.—ED. L.

[1] The Practitioner, September, 1878.

SALICYLATE OF QUININE.

To the Editor of THE LANCET.

SIR,—Perhaps you will allow me, by way of supplementing my remarks on salicylate of quinine, to state that during the last two or three weeks I have had several favourable opportunities of further testing the value of this medicine.

I have had no case of acute rheumatic fever wherein to administer it. My cases have rather been mild, subacute gouty, or rheumatic-gouty, with erratic pains, muscular and articular. In one case of chronic gout, in a lady beyond the middle term of life, I had to discontinue the medicine in consequence of headache, which it was supposed to occasion. In all the others the effect has been satisfactory, and in four remarkably striking, the patients themselves commenting on its success, and asking to be allowed to have recourse to it again should necessity arise.

I would more particularly briefly narrate one case. It is that of a young gentleman, the descendant of an eminently gouty family. Both grandfather and father have been so afflicted for a large portion of their lives. The father, still living, and between seventy and eighty, has had gout for at least forty years. The son, my patient, aged thirty-three, had his first attack of gout two years ago. It was an acute attack. One foot and great toe, especially, were the seat of the affection. Since that time he has only had slight threatenings. Recently, however, he observed that he was becoming rapidly and uncomfortably stout. His hands and fingers, his feet and his toes, were swollen and puffy, and he was unable to write with comfort. Being private secretary in a department of H.M.'s service, at a very busy time, it was important that he should be able to discharge the pressing duties of his secretaryship. Medicines which used to benefit him seemed of comparatively little avail now. I had just come to know the benefit of salicylate of quinine, and I brought it into requisition. I administered it in three-grain doses every six hours. The result was as rapid and satisfactory as anyone could desire, for in the course of thirty-six hours the swellings had nearly quite disappeared. He soon became quite well.

I may state that in all the cases where I have employed this salt no other medicine whatever was used.

I am, Sir, your obedient servant,

Chester-square, April 5th, 1880. ARCHIBALD HEWAN.

*** In reference to the difficulty of obtaining salicylate of quinine, mentioned in Dr. Hewan's former letter (THE LANCET, April 3rd), we have received communications from Messrs. Young and Postans, and Messrs. Gale and Co.—ED. L.

CHIAN TURPENTINE FOR CANCER.

To the Editor of THE LANCET.

SIR,—As Mr. Clay does not make it quite clear whether he regards his experiments with Chian turpentine in the treatment of cancer as absolutely new or merely as revivals, you will perhaps permit me to state that turpentine is not a novel remedy for this disease. During some recent consultations, for a purely literary purpose, of Paracelsus' writings, I encountered in the "Chirurgia Magna," and elsewhere, many references to the treatment of the various forms of cancer, ulcer, fistula, &c., by means of balsams, resins, and turpentine, both as local applications and as internal medicines. I do not remember to have met with the precise mention of Chian turpentine, but the list of "turpentines" given in the second book "De Præparationibus" makes it almost certain that Chian turpentine was included. In the works of Riverius, into a translation of which I casually looked on reading Mr. Clay's paper, turpentine,

Digitized by Google

bdellium, myrrh, &c., are recommended for the cure of cancer of liver, spleen, womb, and other organs.

I am, Sir, yours truly,

Harley-street, W., April 6th. JOHN TWEEDY.

A CASE OF EARLY PREGNANCY.

To the Editor of THE LANCET.

SIR,—As the following case appears to me to possess some interest, I am induced to call attention to it. Although there are cases of pregnancy on record as occurring in England at an earlier age than the following, yet the girl in this instance was so extremely young, and parturition proved so unexpectedly easy, that the matter seems worthy of being recorded :—

L. E—— (born February 7th, 1867, daughter of a farmer) was brought to me in November last to be treated for amenorrhœa. I learned from her mother that the menstrual flow, which had made its first appearance during the preceding April, had not occurred since. Struck by the peculiar figure of the girl, I inquired of the mother whether she had any suspicion of the nature of her daughter's condition, and I then elicited that it had recently come to the knowledge of the parents that there had been an improper intimacy between her and a lad of twenty, employed as farm servant. In consequence of this I made an examination, which verified my suspicion that she was pregnant. I may here mention that the affair became subsequently the subject of criminal proceedings against the lad, who in January last was sentenced to a term of twelve months' imprisonment under the provisions of the recent Act of Parliament.

Although L. E—— was more developed than are most girls of the same age, I naturally anticipated, from her extreme youth, a very tedious if not perilous labour. The sequel will show how agreeably I was disappointed.

On the morning of Feb. 26th I was sent for to visit her, and on reaching the house learned that labour had commenced the previous morning at about half-past ten o'clock. At the time of my arrival (8.30 A.M.) I found the os uteri fully dilated and the head presenting in the first position. From that point labour progressed rapidly, and in one hour and a half terminated in the birth of a healthy, well-developed male child. The mother never had a bad symptom, and both she and the child have been doing well since.

It will be seen from the above dates that L. E—— was, on the birth of the infant, thirteen years and nineteen days old.

I remain, Sir, your obedient servant,

ALBERT E. MAY, L.R.C.P. Ed., &c.

Moreton-Hampstead, March 16th, 1880.

THE BEARER CORPS IN SOUTH AFRICA.

To the Editor of THE LANCET.

SIR,—Although it is a matter of very secondary importance to anyone as to which was the first Bearer Company in action in the late war in South Africa, yet as it appears to have been made a matter of moment by Surgeon-Major Scott in his recent letter to THE LANCET (p. 266), I may remark that a regularly-organised company of Kroomen belonging to the Naval Brigade, previously trained by Fleet Surgeon Norbury, R.N., C.B., was in action with that officer at the battle of Inyezane in January, 1879, and besides this, there was also a large number of trained Native Bearers.

I am, Sir, yours faithfully,

JOHN BOWDEN TRIGGS, M.B., Surgeon R.N.,
In Medical Charge of H.M. Flag-ship *Active* during the late war.

Royal Naval Hospital, Cape of Good Hope, March 15th, 1880.

HONORARY QUEEN'S CADETSHIPS.

To the Editor of THE LANCET.

SIR,—There are a certain number of cadetships given every year at Sandhurst, called "honorary Queen's cadetships." These are not to be confounded with "Queen's cadetships." The first-mentioned are boons conferred on officers' sons whose fathers have done good service in the army, and the holders have only to "qualify," and not to "compete," for their commissions. By the warrant these boons are limited to the sons of the so-called "combatant" officers. The sons of medical officers are excluded from them, no matter what good service their fathers may have done. This is most unjust.—Yours, &c.,

March, 1880. I.V.R.C.

PARIS.

(From our own Correspondent.)

THE proposal to create a new chair of Pathological Anatomy has met with the greatest opposition on the part of the Faculty of Medicine. The professors have all signed a report, which has been sent into the Minister; and they have concluded that the proposed innovation is unnecessary, and that it may be dangerous. It is of course true that it is not absolutely necessary to appoint a new *professor* for this purpose; a post of less importance, such as that of *chef des travaux anatomo-pathologiques*, might be sufficient, and in this manner the wounded susceptibility of the faculty would be soothed. It is also true that such a precedent might prove dangerous to the interests of the present professors, who have every reason to keep their number as restricted as possible. But as far as teaching is concerned, this report is simply a quibble; some change is greatly needed. At the present time practical morbid anatomy is not taught at all in Paris. Post-mortem examinations are only held at the caprice of the house-surgeons and physicians, and that so irregularly, that a student might pass weeks on the look-out for an autopsy. Paris is not only behind Europe in this respect, but also far behind some of the French provincial schools. At Nancy, autopsies are performed in all cases by a competent pathologist, M. Feltz, the professor of anatomy. In Lyons, similar functions are performed by M. Pierret; and at Lille, by M. Kelsch. There is one reason against the new creation in Paris which, although freely whispered, has not yet been stated. The professor who was designed for the chair by the Minister of Public Instruction, M. Cornil, whose work in connexion with morbid histology is well known, happens to be a member of the Chamber of Deputies. The Faculty of Medicine affects the belief that the whole affair looks very like a job, and is afraid that it would afford a precedent for the future creation of new chairs, to suit the convenience of Ministerial favourites. It will be a great pity if the opposition of the Faculty be allowed to prevail. However the wire-pulling may have been conducted, there can be no doubt that some radical improvement is urgently required.

The Société de Médecine Publique et d'Hygiène Professionelle are going to discuss the proposition of one of their members, Dr. Bourgeois, that the State should take measures to prevent the marriage of individuals suffering from certain hereditary diseases which are most generally transmitted to the offspring. According to Dr. Bourgeois, by the prohibition of such ill-advised alliances, phthisis, epilepsy, and mental disease would soon be exterminated. The commission appointed to examine and report upon the proposition, has, as might be anticipated, concluded against it. In the French law there is only one case in which an individual is incapable of contracting marriage, and that is in the case of an *interdit*—that is, a person interdicted on account of mental incapacity from the exercise of civil rights, and this is on legal, rather than on hygienic grounds. For a marriage to be legal consent must be given, and as an *interdit* cannot legally give a valid consent, he cannot contract marriage. Dr. Bourgeois would have every candidate for wedlock submit to medical examination, and would allow marriage to those only who had obtained a medical licence. He also thinks that a difference of twenty-five years between the ages of the two parties should constitute an absolute bar to their union when one of them is over sixty, so that a man of that age would be forbidden to marry a woman of four-and-thirty.

The *République Française* of this day relates a remarkable freak of nature which has occurred at Cherbourg, and which it copies out of the *Vigie de Cherbourg*. If the *République Française* were not always of the most respectable prosiness, one might suppose that it was trying to get off what Artemus Ward would call a "goak." The "infant phenomenon" in question is a child, six months old, and the *Vigie* seems proud that Cherbourg should be privileged to show a marvel

Digitized by Google

which "is without doubt unique since the creation of the world." This child has a spot upon its head out of which grows a feather every six days. The editor of the *Vigie* states that he has seen all the preceding feathers, and that he has assisted at the growth and fall of one of them. A pimple forms on the nape of the child's neck which soon opens and gives exit to the feather, which attains its full length of 10—12 centimetres in six days, and then falls. It has golden edges, and is of the most beautiful and varied hues. The father of this child is coming to Paris to show his interesting babe to the members of the Academy of Medicine. I leave the entire responsibility of this statement with the *République Française*, which must either have copied innocently from the *Vigie* of April 1st, or have maliciously conspired with its provincial contemporary to poke fun at a scientific body of inoffensive old gentlemen.

Paris, April 7th, 1880.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the primary examination in Anatomy and Physiology at Meetings of the Board of Examiners on Monday, Tuesday, and Wednesday last:—

Harry Swift, W. C. Bull, Arthur D. Roe, J. B. Hurry, Henry W. Pigeon, Edward Harrison, and John C. Aldred, Cambridge and Liverpool Schools; John H. Baker, David H. Barley, Anthony Dodd, Robert H. Rowell, Henry M. Fenwick, Newcastle-on-Tyne College of Medicine; John S. Moreton, George Preston, John S. Withers, James Richmond, Thomas L. Jordan, Charles S. Chadwick, Richard Holton, John J. Berry, John M. Beverley, Alexander Wilson, Joseph Collier, Cedric Challinor, and Alfred Hall, Owens College, Manchester; Walter G. Garman, Thomas P. Lowe, G. G. Jones, and Arthur H. Wilson, Liverpool; Charles F. Coombe and Edward France, Sheffield; Arthur Bowe, George Millhouse, John Dacre, Walter Scatchard, Henry Pope, and Eustace G. Carter, Leeds; Henry Shillito, Septimus Sunderland, John H. North, James R. Polson, and William Joberns, Birmingham; Lawrence E. A. Salmon, William H. Francis, Bristol; William J. Haddock, Charing-cross Hospital; John Hosford, Cork; Francis H. Furnival and Sandford S. Lessey, St. Thomas's Hospital; F. F. Schacht, St. George's Hospital; Samuel Aspinall, St. Mary's Hospital; John T. Tibbles, Charing-cross Hospital; Wheelton Hind, Guy's Hospital; Charles E France, Middlesex Hospital; Sidney H. C. Martin, University College; and Edwin J. Wenyon, Guy's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 1st:—

Adams, Joseph, Royal Infirmary, Edinburgh.
Davies, Jenkin, Sidney-road, Stockwell.
Fraser, Donald Alexander, Weston-super-Mare.
Walters, Fredk. Rutenacht, The Waldrons, Croydon.
Wheeler, Fredk. John, Grafton-road, Holloway.

The following gentlemen on the same day passed the Primary Professional Examination:—

Charles Rowland Ordish Garrard, Guy's Hospital; Robert Henry Rowell, Newcastle-on-Tyne.

THE annual Report of the Leeds General Infirmary unfortunately shows a balance due to the treasurer of £3911; with a gradual decrease of income, and an increase in the number of patients.

A SPECIAL appeal for funds has been put forth by the Finance Committee of Addenbrooke's Hospital, Cambridge. The 30th of May has been fixed as the Sunday on which collections are to be made on behalf of the institution in the different churches and chapels of the town.

ZYMOTIC DISEASES IN DUBLIN.—During the March quarter small-pox caused 61 deaths; measles 95; scarlatina 186; diphtheria 13; whooping-cough 106; fever 76; and diarrhœa 34.

VACCINATION GRANTS.—The following gentlemen have received Government grants for successful vaccination in their respective districts:—Dr. Cuolahan, of Bermondsey, £127 12*s.* (fourth award); Mr. W. Powell, of the Bromyard Union (second award); Mr. J. H. Hynes, of the No. 2 District, Nottingham Union, £55 14*s.* (second award).

ADMIRALTY APPOINTMENTS.—Staff-Surgeons T. C. Hickey to the *Resistance*, Septimus Evans to the *Impregnable* for service in the *Neptune*, and Joseph Wood to the *Himalaya*; Surgeons William Tait to the *Impregnable* for service in the *Rifleman*, J. Dunlop to the *Orwell*, and R. W. Williams to the Plymouth Division of the Royal Marines.

ABERDEEN DISPENSARY.—At the annual meeting of the friends of this charity it was announced that there had been, during the past year, an increase of 470 in the number of patients. The important part played by wholesome and nutritious food in the treatment of the sick poor was shown to be especially recognised by the medical officers in that they had recommended to the Society for the Improvement of the Condition of the Poor, eighty-two persons, of whom sixty had received food and clothing. Complaint was made—and justly—by the chairman of the meeting of the smallness of the amount of subscriptions in the past year—viz., £96—a sum certainly not creditable to the citizens of Aberdeen.

PHYSICAL BASIS OF LIFE.—On Monday evening, at a Meeting of the Victoria Institute, held at 7, Adelphi-terrace, a paper by Professor H. Alleyne Nicholson, M.D., D.Sc., F.R.S.E., who fills the chair of Natural History in the University of St. Andrews, was read, the subject being "Life and its Physical Basis." It discussed the physical and chemical properties of the substance known as protoplasm, which forms the common basis of all organic bodies; the phenomena exhibited by simple masses of protoplasm in a living condition (such as the monera, the amœba, and the yeast plant); the distinctions between dead protoplasm and living protoplasm; the nature of vitality; and the essential character of the temporary connexion which subsists between protoplasm and life. A communication bearing on the latest researches in this recondite branch of natural history, from Professor G. G. Stokes, F.R.S., of Cambridge, was also read, and a discussion followed.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. Thomas Wrigley, of Timberhurst, Bury, bequeathed £10,000 each to Owens College, the General Hospital for Sick Children at Pendlebury, the Royal Albert Asylum for Idiots and Imbeciles of the Northern Counties at Lancaster, and the Bury Dispensary. Mr. Duncan MacDermid, and Miss Margaret MacDermid, his sister, bequeathed £500 to the Royal Infirmary, £500 to the Western Infirmary, and £200 to the Convalescent Home, all at Glasgow, and £200 to the Institution for Imbeciles at Lanbert. Sir Thomas Bernard Birch, Bart., of the Hazels, Prescot, bequeathed £300 to the Liverpool Infirmary, £200 to the Liverpool Dispensaries, £100 to the Liverpool Northern, and £100 to the Liverpool Royal Southern Hospital. Miss Mary Wasey, who recently died at Prior's Court, Chieveley, near Newbury, has bequeathed £3000 to the Royal Berkshire Hospital at Reading, £2000 to the Bath Hospital, £2000 to the Cancer Hospital at Brompton, and £2000 to the Consumption Hospital, Brompton.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

BOOTH, J. M., M.B., C.M., has been appointed Medical Officer to the Aberdeen Dispensary, vice Simpson, resigned.

BRANDER, J., M.B., C.M., has been reappointed Medical Officer to the Aberdeen Dispensary.

CLARK, J. G., M.R.C.S.E., L.S.A.L., has been appointed Clinical Assistant to the Medical Out-patient Department of the London Hospital.

ELLIOT, J., L.R.C.P.Ed., has been appointed Medical Officer to the First District and Workhouse of the Bellingham Union, vice Hill, resigned.

FOWLER, J. K., M.B., has been appointed Assistant-Physician to the Middlesex Hospital.

GANGE, F. A., M.D., has been appointed Medical Officer of Health to the Faversham Rural Sanitary Authority.

GARDEN, R. J., M.D., C.M., has been reappointed Medical Officer to the Aberdeen Dispensary.

GRAHAM, A., L.R.C.P. &c., has been appointed Medical Officer to the Western Division of the Bingham Union, Notts, and District Surgeon to the Midland Railway Company's Friendly Society, Nottingham and Melton Line.

HALL, J. G., M.B., C.M., has been reappointed Medical Officer to the Aberdeen Dispensary.

HOLDEN, J. C., M.D., L.R.C.P.Ed., has been appointed Physician to St. Leonard's Hospital, Sudbury.

HOLDERNESS, W. B., has been appointed Surgeon to the Royal Infirmary, Windsor, vice Fairbank, deceased.

JONES, R. T., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer to the Llanfihangely-Traethau District of the Festiniog Union.

KNIGHT, J. T., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Carlton District of the Basford Union.

LILLEY, G. H., M.D., has been appointed Assistant-Surgeon to Her Majesty's Convict Prison, Parkhurst, Isle of Wight.

Digitized by Google

LYNCH, J. C., M.R.C.S.E., L.S.A.L., has been reappointed Surgeon to St. Leonard's Hospital, Sudbury.

MACLEAN, H., M.D., has been appointed Medical Officer to the First District of the Romford Union, vice Wright, resigned.

MURRAY, J., M.A., M.B., has been appointed a Surgeon to the Northern Infirmary, Inverness.

OGSTON, F., M.D., L.R.C.S.Ed., has been reappointed Medical Officer to the Aberdeen Dispensary.

PICKFORD, J. K., M.R.C.S.E., L.R.C.P.L., has been appointed Medical Officer to the Workhouse of the Leeds Union, vice Rhodes, resigned.

PURNELL, T., M.D., L.R.C.P.Ed., M.R.C.S.E., has been reappointed Medical Officer of Health for Wells Urban Sanitary District.

ROBERTSON, R., M.D., has been appointed Physician to the Liverpool Workhouse and Fever Hospital, vice R. Gee, M.D., appointed Consulting Physician.

ROWLANDS, J. F., M.R.C.S.E., has been appointed Medical Officer of Health for Richmond, Surrey.

SHAW, W., M.B., C.M., M.R.C.S.E., has been appointed House-Physician to the North Staffordshire Infirmary, vice McAldowie, resigned.

SHIELD, J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Fourth District of the Romford Union.

SMITH, P. B., M.D., C.M., has been reappointed Medical Officer to the Aberdeen Dispensary.

TAYLOR, H. C., M.B., M.R.C.S.E., &c., has been appointed Assistant Medical Officer to the Royal Albert Asylum for Idiots and Imbeciles of the Northern Counties, vice D. T. Playfair, M.B., resigned.

TERRY, C., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer to the Third District and the Workhouse of the Newport-Pagnell Union.

THAW, E. P., M.B., C.M., has been appointed Medical Officer of the Lesbury District of the Alnwick Union.

THOMSON, W. A., F.R.G.S., has been appointed Surgeon to the Midland Railway Company, for the Ampthill, Flitwick, and Harlington Districts.

WILLIAMSON, W. H., M.B., C.M., D.D.S., has been appointed Dental Surgeon to the Aberdeen Dispensary.

Births, Marriages, and Deaths.

BIRTHS.

DUNLOP.—On the 26th ult., at 50, David-place, St. Helier's, Jersey, the wife of Andrew Dunlop, M.D., of a son.

GOULD.—On the 4th inst., at 10, Queen Anne-street, Cavendish-square, the wife of Alfred Pearce Gould, M.Ch., of a daughter.

KAVANAGH.—On the 3rd inst., the wife of P. Kavanagh, M.D., of Wickham-road, of a daughter.

LESSON.—On the 6th inst., at Cotehall, Twickenham, Margaret, wife of J. Rudd Lesson, M.B., of a daughter.

SYMES.—On the 1st inst., at Ward's End, Halifax, the wife of Edmond West Symes, M.D., of a son.

MARRIAGES.

BRASH—GREGORY.—On the 6th inst., at St. Mary's, Tedburn, by the Rev. Charles Tothill, Rector, Edward A. Brash, M.R.C.S.E., L.R.C.P.L., only surviving son of the late James Brash, Esq., late 82nd Regiment, to Blanche, second daughter of J. B. Gregory, Esq., of Colley House, Tedburn St. Mary.

CHAWNER—CLOWES.—On the 31st ult., at St. Barnabas, Kensington, by the Rev. Albert Clowes (uncle of the bride), Alfred Chawner, L.R.C.P.L., &c., of Ashover, Derbyshire (son of the late Rev. W. Chawner, Vicar of Crich, Derbyshire), to Emily S. L., eldest daughter of William Clowes, Esq., Chancery Registrar, 80, Holland-road, W.

CROCKER—FUSSELL.—On the 3rd inst., at St. Nicholas Church, Brighton, by the Rev. T. Lee, Vicar of St. John the Baptist, Islington (uncle of the bride), assisted by the Rev. F. Brealey, late Vicar of Easingwold, Henry Radcliffe Crocker, M.D. Lond., M.R.C.P., of 28, Welbeck-street, W., to Constance Mary, only child of Dr. Fussell, of Brighton, and granddaughter of the late Henry Austin Fussell, of Sanford House, South Wilts.

ELLIOT—BAINBRIDGE.—On the 6th inst., at St. Paul's Church, Whitley, by the Rev. John S. Nye, assisted by the Rev. F. Rales, Henry Elliot, M.R.C.S.E., of Marden, Kent, to Annie, third daughter of the late William Bainbridge, Esq., Barrister-at-law, of Cliff House, Cullercoats, Northumberland.

HARRIS—ASHTON.—On February 26th, at Barkly Diamond Fields, Griqualand West, South Africa, William Lester Harris, L.R.C.P., M.R.C.S.E., L.M., J.P., District Surgeon, to Sarah, youngest daughter of the Rev. William Ashton, Missionary of the London Missionary Society.

SWAIN—ARCHIBELL.—On the 3rd inst., at St. Saviour's Church, Euston, by the Rev. J. D. Hawksley, Edward Swain, L.R.C.P.Ed. &c., Medical Superintendent of the Three Counties Asylum, Arlesey, Beds, to Florence Annie, eldest daughter of the late James Archibell, of Regent's-park.

DEATHS.

ADAMS.—On the 30th ult., at Evesham-street, Bangay, Edward B. Adams, M.R.C.S.E., L.S.A.L.

ROBATHAN.—On the 8th ult., after a lingering illness, at his residence, Main-street, Hyde-park, Pennsylvania, U.S., Dr. John W. Robathan, eldest son of Edward Robathan, L.R.C.P.Ed., M.R.C.S.E., of The Grove, Risca, Monmouthshire, aged 36.

WINSLOW.—On the 1st inst., after a few hours' illness, at Sussex House, Hammersmith, William St. John Forbes, fifth son of Dr. L. S. Forbes Winslow, aged 9 months.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

METEOROLOGICAL READINGS.

(Taken daily at 8 a.m. by Steward's Instruments.)

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

POISONING BY INDIAN HEMP; AUTOPSY.

THE *Indian Medical Gazette* reports a case of death resulting from Indian hemp, some preparation of which the deceased had been accustomed to smoke for many years. After so indulging he generally became insensible or stupid. He was delirious for a fortnight before his death. On the day on which he died he tried to hammer a nail into his temple, and then expired suddenly. The post-mortem examination revealed the following condition:—Body of a well-nourished male, aged about forty years, exhibiting no marks of violence excepting a small lacerated wound, measuring a quarter of an inch across, over right temple. This did not penetrate the muscular aponeurosis. Beneath the occipito-frontalis, and at a point below the wound, there was a large clot of extravasated blood. Skull not fractured. On removing the vault, vessels of diploe and dura mater were seen to be greatly congested. Beneath the dura mater blood was found effused over the whole upper surface of right brain and over the frontal lobe of left brain. A large clot was found in the right middle fossa of skull; this extended across the crus and pons. There was a large clot in the left lateral ventricle; a smaller one in the right. The posterior borders of lower lobe of lungs on both sides were hypostatically congested, otherwise healthy. Cavities of the heart empty; valves competent, healthy. Liver, spleen, intestines, and kidneys healthy. Stomach full of half-digested food; mucous membrane blackened in places from decomposition of blood in distended vessels. Bladder full of healthy urine, but not distended.

Mr. T. Brenton.—The medical and surgical papers in "Cassell's Household Guide" would answer our correspondent's purpose. But all such publications are poor substitutes for good medical advice.

NEEDLES FOR ELECTRO-PUNCTURE.

To the Editor of THE LANCET.

SIR,—In your report of Dr. Ord's paper on a case of "Aneurism treated by Galvano-Puncture," read before the Medical Society of London, a difficulty appears to have arisen with regard to the insulation of the anodal needles. I send herewith a needle, insulated with shellac after a method I have adopted for some years past. As you will observe, the needle has been used for an aneurism of the arch of the aorta), the point being eaten away, and the uninsulated portion much oxydised, yet the insulation remains perfect. The shellac is applied by heat, care being necessary to avoid a too high temperature, as, if the heat be excessive, the lac is covered with microscopic fissures which destroy its cohesion, and render the insulation imperfect. Needles thus insulated may be obtained from Messrs. Mottershead and Co.

Yours, &c.,

Manchester, March 22nd, 1880. J. DIXON MANN.

BROWN INSTITUTION.

IT appears from a Report to the Committee of the Brown Institution for the year 1879, by the Professor-Superintendent, that during the first part of the year the amount of material for clinical and pathological investigation afforded directly by the practice of the Institution was necessarily small, and even since that time comparatively few cases have presented themselves having any special interest. "Of these," Dr. Greenfield observes, "I may especially mention several cases of nervous diseases in domestic animals to which my own attention has been directed. Together with these, many carcases of animals have been sent from all parts of the country for pathological investigation, and have afforded material for study. I have reason to believe that great good is done by this part of the work of the Institution. In many cases the nature of an outbreak of epidemic disease is thus determined with certainty at the outset, and the proper measures can be taken to arrest its progress; and in other cases opportunities are afforded for the pathological investigation of diseases which are rare in towns, or which are obscure in their nature. On these grounds I believe that an extension of this branch of the work would be highly beneficial to the public in general. Apart from these subjects, which more particularly belong to the business of the Institution, I have, with the sanction of the Committee, been much engaged in an inquiry, on behalf of the Royal Agricultural Society, into the nature, causes, and prevention of anthrax and anthracoid diseases. This inquiry is in continuation of those which were so happily initiated by Dr. Burdon Sanderson in 1876, some of which have already yielded such valuable results with regard to pleuro-pneumonia and foot-and-mouth disease. The present inquiry relates to the great class of diseases known as anthracoid, which are not only widely prevalent amongst bovine animals, and more rarely horses, in this country, but affect also sheep, deer, and sometimes man, in many parts of the globe. The forms most common in this country are known as splenic apoplexy and quarter evil respectively; and one very important question is whether these are diverse manifestations of one and the same disease, or in what way they are related. This problem I have endeavoured to solve by the microscopic examination of specimens from a number of cases of these diseases, and of other anthracoid diseases occurring in India and South Africa, by the artificial cultivation of the virus of the disease, and by the inoculation of lower animals (rodents) with the virus. So far as these observations have gone, they appear to show that these various diseases, though allied in the conditions of their occurrence, and in the organism which forms their specific virus, are yet not identical in either of those respects. Moreover, with regard to the forms which differ from splenic apoplexy, I have been able to show that these diseases are communicable by inoculation to rodents, and preserve in them the usual features of the special form of disease from which they were derived; thus rendering it highly probable that these forms are communicable by contagion, and are not merely due to local or climatic causes, as has been supposed. Beyond this, nothing special has been elicited as to the causes of anthrax. The other branch of the inquiry is even more important—viz., the possibility of prevention of the disease (splenic apoplexy) by inoculation of the virus transmitted through rodents. These experiments were suggested by the results of certain preliminary experiments made by Mr. Duguid at the request of my predecessor, which appeared to show, first, that when anthrax is communicated by inoculation to bovine animals through rodents, the animals so infected, although exhibiting severe symptoms, recover; and, secondly, that such animals are less liable than others to future infection by the same process. I have continued experiments in the same direction, varying the method employed, with results which are in the main in striking confirmation of those which preceded. Hitherto I have been unable to perform the crucial experiment of exposure to direct contagion from a bovine animal suffering from the disease arising in the usual manner; but I have inoculated an animal thus protected with a large quantity of blood of a sheep which had died of anthrax, without producing any serious symptoms. Should this method of inoculation be found to succeed, even in a majority of cases, it would afford a most valuable prophylactic measure in those districts where from time to time whole herds of cattle die of the disease. It may, however, furnish another illustration of the pathological law exemplified in the relations of small-pox and vaccinia, and may serve as a basis for future more extended researches in relation to the prevention of fatal epidemic diseases."

HYPODERMIC INJECTION OF QUININE.

DR. MACREDDIE, civil surgeon of Pertabgurh, in Oudh, states the hypodermic administration of quinine to be both efficacious and economical. He employs citric acid, however, as a solvent, in the proportion of five grains to one grain of sulphate of quinia, in a drachm of water. Dr. MacReddie has never met with abscess or ulcer as resulting from the solution. The irritation sometimes arising disappears without treatment.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

AS the mode of conducting the Primary or Anatomical and Physiological Examinations for the diploma of Membership of this institution has been much altered, perhaps the following may be interesting to teachers and students. Commencing with the written portion of the examination, there were two distinct papers submitted to the candidates on the same day (viz., the 2nd instant), from one to three o'clock, when they were required to answer four, and not more than that number, out of the following six questions on Anatomy:—

1. Describe the calcaneum.
2. Describe the arrangement and attachments of the perineal fasciæ.
3. Give the attachments of the trapezius muscle; state what structures are exposed upon its removal.
4. Give the dissection required to expose the first portion of the subclavian artery on the right side.
5. Describe the course and relations of the portal vein; name its tributaries, and mention their anastomoses with the systemic veins.
6. The brain being removed from the skull, how would you proceed to expose the corpora quadrigemina?

These having been answered or attempted, they met again after an hour's respite—viz., from four to six, when the following questions on Physiology were submitted to them, with the same conditions as the Anatomical:—

1. Give the physical characters and chemical composition of the blood; describe its corpuscles. What purposes do they fulfil?
2. Mention the average period of eruption of the temporary and permanent teeth. Describe the minute structure of a tooth.
3. Give a description of the microscopical appearances presented by a transverse section of the spinal cord in the cervical region. What are the functions of the cord?
4. Describe the course and minute structure of a renal tubule. What functions have been ascribed to its several parts?
5. How is the circulation of the blood maintained? What is the average velocity of the blood in the larger arteries and veins, and in the capillaries? By what means has this been ascertained?
6. What is the structure of adipose tissue? What are its uses in the economy? and what are the circumstances that lead to variations in its amount?

Of the 173 candidates, 24 were examined daily at the *vivâ voce* for fifteen minutes at *two* tables, instead of ten minutes at *three*, as heretofore. At these tables there were two examiners in Anatomy and two in Physiology. At the former tables were to be seen carefully-prepared dissections, made by gentlemen who had passed the examination, and the *élite* of the metropolitan schools, as also some beautiful preparations from the museum of the College. At the expiration of the time the candidate proceeded to the Physiological tables, where he was met by two examiners, who submitted to him microscopic objects, such as blood, urine, milk, muscular fibre, bone, enamel, sections of kidney, brain, &c. The examiners in Anatomy were Messrs. Durham and Bellamy at table A, and Messrs. Pick and Rivington at table B; Physiology was represented at table C by Messrs. Power and Lowne; and at D by Messrs. Baker and M'Carthy. The new plan appears to work very well, and to give great satisfaction to the students. Mr. Heath, who is the Chairman of the Board, readily admits Fellows of the College and teachers generally to witness the examinations, which in consequence may be considered public.

A FEW REMARKS ON AN EPIDEMIC OF RUBEOLA.

To the Editor of THE LANCET.

SIR,—I have read with interest Dr. Dyce Duckworth's account of a case of rubeola in your issue of March 13th, as we are passing through an epidemic of this disorder, which first made its appearance amongst us some four months ago. I have had under my care many cases, male and female, their ages varying from sixteen to forty-five years. The case of A. M——, described by Dr. Duckworth, is typical of the generality of my cases. The most striking features of this disorder that I have noticed are—(1) the uncertain manner in which it seems to affect those exposed to the infection, one or two of a large household suffering from it, the others escaping, notwithstanding the absence of all precautionary measures; (2) the incubative period is about fourteen days, the prodromic from one to three; (3) there is little or no discomfort during the existence of the rash, but that intense pruritus often ensues upon its dying away; (4) there is little or no desquamation; (5) the enlargement of the cervical and suboccipital glands, with their excessive tenderness, is often the first condition that indicates that a person is out of sorts; (6) this lymphatic irritation is out of all proportion to the amount of pharyngeal congestion or other local causes. I might remark that we have had concurrently with this outbreak of rubeola an epidemic of true measles. From this and the fact that nearly all my patients suffering from the former can give a definite account of having had measles, however heretical it may seem, one is led to wonder whether this so-called rötheln is not morbilli, modified by a previous attack. My treatment has been warm baths with saline aperients. All my cases have terminated satisfactorily.

I remain, Sir, yours &c.,

Kingsbridge, April 2nd, 1880. W. H. WEBB, M.R.C.S.

Mr. J. Robertson.—The matriculation examination at the Royal Veterinary College, London, is as follows:—A pupil, previously to his admission, is required to produce a recognised certificate of educational requirements, bearing date within the past four years. This certificate must include all the pass subjects of the matriculation examination, or otherwise he must pass an examination in writing, reading aloud, dictation, English Grammar, English History, Arithmetic, and French or Latin. A pupil may elect to be examined in any of the following subjects:—Euclid, Algebra to Quadratic Equations, Geography, Natural History, Physiology, Chemistry, Physics, and the Greek, German, or Italian Languages. The usual age for entering a veterinary school is eighteen years. There are two schools in Edinburgh, one in Glasgow, and one in London. All are affiliated to the Royal College of Veterinary Surgeons, the licensing body.

Mr. E. Winterborne.—In such a case the disease must, without doubt, be regarded as inherited. Epilepsy, which is in part the result of inherited taint, may commence at any period of life, as Dr. Gowers has shown in the lectures now publishing in our columns.

Dr. W. R. Smith, (Cheltenham.)—The paper will appear in an early number.

IS JAGGARY AN ANTISCORBUTIC?

To the Editor of THE LANCET.

SIR,—Surgeon Cullimore, in your impression of March 27th, exhibits surprise at the inferences I drew from his letter of January 31st, "On the Remedial and Preventive Effects of Molasses in Scurvy," &c. Here is the sentence which led me to believe that he had adopted the theory that sea influences and salt provisions are *per se* causative of scurvy: "Thus impressed by memory, and being surrounded by disease of a scorbutic character, though brought about by causes far removed from sea influences and salt provisions (these latter cannot be set down as causes of scurvy in the Indian famine, as the very bullocks often died from *want of it* ["sea influences and salt provisions," or "disease of a scorbutic character"?] owing to the heavy salt tax; it was due more to starvation, and to the effects of roots, nuts, wild aloe, prickly pear, and such inedible matters)." From the foregoing I concluded Surgeon Cullimore implied that (1) sea influences and salt provisions are the usual causes of scurvy; (2) that at sea the excessive use of salt is the prime cause; but that (3) in the Madras famine scurvy was due more to starvation, and to the effects of roots, nuts, wild aloe, and prickly pear. These conclusions may seem "illogical and incomprehensible," but they seem at least natural.

As to the bullocks exhibiting strong political feelings, and dying as a result of the "heavy salt tax," the question is hardly one to engage your space with; but I must say that Surgeon Cullimore's experience must have been cast in happy places to have discovered that, even in the most prosperous times, the average ryot gives to his bullocks one atom of salt from one year's end to another.

I am sorry I was not sufficiently logical to comprehend that your correspondent's experiments were intended to prove the "assimilation-assisting" power of jaggary, and confess I somewhat lost myself in following his statements as to the "powerful calorifacient, antiscorbutic, and assimilation-assisting properties of jaggary"—*multum in parvo!* But now that I do know that his experiments were advanced in proof of the latter quality only, I must still be allowed to point out that even on this count they cannot be considered to carry conviction. A gaol surgeon of the most slender experience usually knows that for a short time after admission prisoners fall off in weight; hence the comparison between twelve men received into a famine camp and twelve lately arrived inmates of a gaol is fallacious, and hence also Surgeon Cullimore's observations may be regarded as "practically worthless."

To bring into greater relief the alleged assimilation-assisting properties of jaggary, your correspondent states "it was the general experience that the chronically starved lost weight for at least a week after admission" into famine camps, "*no matter how well fed*, unless sugar was given." Well, Sir, this may be that gentleman's experience stated again in a "general way," but, after a careful series of weighings undertaken with reference to gain of weight on certain diets in periods of time, this certainly was not mine; that is to say, provided that patients were selected and placed upon diet considered suitable for their individual requirements, so as to obviate as far as possible the risk of intestinal complications. In the case of prisoners, there exist well-recognised reasons why they may be expected to fall off in weight for a short time; but with the famine-stricken, the change from a wandering life of beggary, bereft of food and shelter, to one of comparative ease and luxurious feeding, should surely be followed by progressive increase of weight. Can your correspondent state why his patients were so "illogical and incomprehensible" as to obstinately refuse not only to be benefited by food under favourable circumstances, but actually to *fall off in weight* for a whole week? In the meantime, it is not, I think, "beyond the bounds of imagination" that "a sane person" should believe that these experiments, as formerly suggested by me, simply demonstrate a fact known to the cattle-breeder in this and in other countries, that when saccharine bodies are added to an otherwise full diet increase of weight will be obtained.

As to the alleged antiscorbutic properties of molasses, Surg. Cullimore would fain regard the evidence of the New England sea-captains and that of Dr. Buzzard as conclusive. That of the latter would certainly be entitled to the greatest respect, if capable of the interpretation your correspondent would desire; but I question if Dr. Buzzard would care to have his testimony coupled with that of even "practical men," who declare that molasses is *more efficacious* than lime-juice. As a useful addition to the diet of imperfectly-fed soldiers, no doubt it was employed with "decided benefit"; but I see nothing in Dr. Buzzard's communication that could be regarded as incompatible with the belief that its action was otherwise than due to an increase in the total nutritive power of the diet produced by such an addition, and thus effected a modifying influence in cases of scurvy. Indeed, Dr. Buzzard's testimony would go strongly against employing it in the case of the famine-stricken (the position assumed by Surgeon Cullimore), as he distinctly points out that intestinal affections were apt to arise as a result of its use; so that it is evident, even if he believed in molasses as an antiscorbutic, he would not agree with your correspondent as to its "assimilation-assisting property," or that either result would be effected by a "partial acetous fermentation."

Surgeon Cullimore evidently considers that in asking me if I have used jaggary he puts a crucial question, which, if not answered in the affirmative, I should be bound for ever to hold my peace on the ground that my criticisms are "practically worthless." Well, Sir, if this notion is tenable, the sooner you desert your desk the better, for I am much afraid that you have driven THE LANCET before now through many a pretty theory without having seen the practice advocated in its support carried out. Might not your correspondent have concluded that in my experience as a famine-wallah, I must have seen something of a remedy that by his recommendation was introduced "generally among the famine-stricken people of the Madras Presidency?" But, Sir, I did not use it, nor did I see it used. I was, however, aware of Surgeon Cullimore's advocacy of jaggary, and, now I am making a confession, let me add, nothing came to my knowledge to lead me to consider it necessary to abandon established antiscorbutics in favour of what I considered, and consider, would in a famine-stricken subject give rise to intestinal affections. Surgeon Cullimore may, perhaps, be able to show statistics on this latter point. A remarkable absence of diarrhœa and dysentery in camps where jaggary was used as contrasted with others, would be of decidedly more value in proving its assimilation-assisting properties than the two bald and fallacious experiments he has advanced.

Your obedient servant,

April, 1889. A MADRAS FAMINE-WALLAH.

HICCOUGH.

DR. J. S. WARREN, of Danville, Ky., offers, as an explanation of the relief afforded to hiccough by holding the breath as long as possible, the following theory: "By holding the breath the trisplanchnic nerve is held in abeyance until the pneumogastric, which is off guard, can get back to its post."

Mr. G. S. Davies.—Messrs. Williams and Norgate would probably be able to supply the published monographs on the subject; but, as much of the "literature of septicæmia" is to be found only in journals and in Transactions of Societies, some library—e.g., that of the Royal College of Surgeons—should be consulted.

E. C. G.—Small books of Questions have been published by Gant, Lush, Husband, &c.

J. H. B.—Safranine, one of the red aniline dyes, has been recommended for the detection of amyloid matter.

Dr. John Anderson.—Henle's Anatomy is the best. We know nothing of the Surgery or Medical Dictionary.

Inquirer.—The Habitual Drunkards Act.

CASE OF OBSTINATE SCIATICA RELIEVED BY STRETCHING OF NERVES.

To the Editor of THE LANCET.

SIR,—The following case, which was under the care of Dr. Robertson may be of interest:—

D. F——, a blacksmith, aged forty-five, had for eight months suffered from sciatica of such severity as to entirely unfit him for work during that period. The paroxysms of pain were very frequent and intense, and his general health had been much impaired. No improvement following the exhibition of ordinary remedies, he became an inmate of the Glasgow Western Infirmary, where he remained for ten weeks. During his stay in the hospital he had blisters applied repeatedly over the course of the nerve without benefit; and the paroxysmal pains being still undiminished as to their frequency and violence, the actual cautery was resorted to, but failed to lessen his suffering. The daily use of galvanism for three weeks afforded not even temporary immunity from pain, and he quitted the hospital in no sense relieved, having refused to undergo the operation of stretching. Two weeks after his return home he consented to the operation being performed. Accordingly, having been brought under the influence of chloroform, an incision, two and a half inches in length, was made midway between the major trochanter and ischial tuberosity; the nerve was easily exposed and hooked out by the fingers. It was then firmly stretched until a degree of relaxation was obtained, extension of the limb being at the same time maintained. The wound was brought together with wire sutures, and antiseptic dressing applied. A good deal of suppuration followed, due, doubtless, to the comparatively low vitality of the tissues involved. Since the operation, twenty-two days ago, he has had no return of the paroxysms, and complains of no pain other than that referable to the wound.

Yours &c.,

Dumbarton, March 22nd, 1880. MAULE RICHARD, L.F.P.S.G.

SPECIALISM.

THE New York *Medical Gazette* takes note of the increase of specialism in the States, and while acknowledging that there is some good purpose served in medical practice by a limited exercise of the principle of division of labour, objects, as we have often done, to its excessive development, as calculated to narrow the range of perception in diagnosis, and consequently to injure medicine as a healing art.

Mr. T. Beaufoy Green.—There is no rule to guide in such a question. The time occupied is an important element to be considered, of which our correspondent says nothing. He is himself the best judge. But he must not underrate the importance of such duties.

VOTING PAPERS FOR UNIVERSITIES.

To the Editor of THE LANCET.

SIR,—If your correspondent Mr. R. V. Ash, or any other gentleman qualified to vote, will communicate with the Secretary of either of the Committees in London, he will, no doubt, be enabled to get his voting-paper duly signed by a J.P. Mr. Hedderwick, 2, Fairfield-court, Temple, has, I know, made such arrangements in behalf of the Liberal interest. The voter can have his paper signed by taking with him some one known to the magistrate.

Respectfully yours,

April, 1880. J. C.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Vinen, London; Dr. G. Johnson, London; Dr. Greenfield, London; Mr. Dewar, London; Mr. Morrant Baker, London; Dr. J. Cavafy, London; Mr. Robertson, Southport; Dr. W. THE

Lumleian Lectures

ON

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.

Delivered before the Royal College of Physicians,

BY WM. ROBERTS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL MEDICINE TO THE OWENS COLLEGE.

LECTURE II.—PART I.

PEPSIN AND TRYPSIN—DIGESTION OF PROTEIDS.

VARIOUS kinds of albuminous or proteid substances are used by mankind as food. The most important of these are muscular flesh, the casein of milk, and egg-albumen from the animal kingdom; and gluten, albumen, and legumin from the vegetable kingdom.

Proteids are attacked by the digestive ferments at two points in the alimentary canal, by pepsin in the stomach, and by trypsin in the small intestine. Between these two acts of digestion there is a complete break in the duodenum, owing to the abrupt change of reaction from acid to alkaline which occurs at that point.

Gastric digestion is, in all creatures, an essentially acid digestion; but the most varied opinions have been entertained as to the nature of the acid. It has been supposed in turn to be hydrochloric acid, lactic acid, acid phosphate of lime, butyric, and even acetic acid. Much of this confusion has arisen from not distinguishing between the acid of pure gastric juice as secreted into an empty stomach, and the acid of the gastric contents during the digestion of a meal. A good deal of light has been thrown on this subject by the recent researches of C. Richet.[1] This observer found himself in exceptionally advantageous circumstances for the study of the gastric juice. He had under observation a young man on whom Verneuil had successfully performed the operation of gastrotomy for the relief of impermeable stricture of the œsophagus, the result of swallowing inadvertently a quantity of caustic potash. The complete occlusion of the œsophagus enabled Richet to obtain and examine the gastric juice in a pure state, uncontaminated with saliva. All food had to be administered through the fistulous opening left after recovery, and the observer could at any moment—as in the famous case of Alexis St. Martin—withdraw portions of the gastric contents for examination. Richet also took advantage of the new method of separating the various organic and mineral acids from one another made public by Berthelot in 1872.[2]

Berthelot had found that if you shook up an aqueous solution of any acid with ether, and then allowed the two fluids to separate, that a part of the acid passed into the ether, and that the remainder clung to the water, and that the ratio between these two parts was a constant quantity. He called this ratio the *coefficient of partage*, and found that its value was a fixed characteristic for each particular acid. Solutions of the mineral acids were found to yield nothing, or almost nothing, to ether when agitated with it; but organic acids were found to pass into the ether in considerable, though very variable, quantities—the proportion varying in a constant ratio according to the nature of the acid.

Testing pure gastric juice, uncontaminated with food or saliva, by this method, Richet found that almost all the acid was retained by the water, and that only a small proportion—about one in twenty-two—passed into the ether. This showed that the acid of pure gastric juice was almost entirely a mineral acid, with only a minute admixture of organic acid. The organic acid (tested by the same method) exhibited a coefficient of partage closely corresponding with that of sarco-lactic acid. The nature of the mineral acid was determined by a method similar to that employed by C. Schmidt, and yielded the same result—namely, undoubted evidence that the mineral acid of pure gastric juice was hydrochloric acid. But Richet found that this mineral acid did not behave in the presence of salts of the organic acids quite in the same way as free hydrochloric acid does. The observations of Berthelot had shown that when free hydrochloric acid is added to a solution of acetate of soda, or other similar organic salt, the mineral acid attaches the base entirely to itself, and throws the whole of the organic acid free into solution—so that the mixture when tested by the method of coefficient of partage behaves exactly like an unmixed solution of the organic acid. When pure gastric juice was put to this test it was found that, although it liberated the organic acid largely, it did not do so to the same extent, by a good deal, as if the mineral acid contained in it had been entirely free. It behaved, rather, as hydrochloric acid does when united with a feeble organic base, such as leucin or peptone—and, on the ground of what appear to be very careful experiments, Richet came to the conclusion that this feeble base was probably leucin, derived from the gastric mucus, and that the acid of pure uncontaminated gastric juice was hydrochloric acid in loose combination with leucin.

Richet next proceeded to examine the free acid actually existing in the stomach during the digestion of a meal in his patient with gastric fistula. He found, as might have been expected, that this differed from the acid of pure unmixed gastric juice—in this respect, namely, that it contained a very much larger proportion of organic acids, in comparison with the mineral acid, than pure gastric juice. It was evident that the mineral acid had to a large extent seized upon the bases of the acetates, malates, lactates, butyrates, and other organic salts always present in the food, and had set free their organic acids. The real work of digestion then, so far as the acid constituent is concerned therein, is largely performed by various organic acids thus set free from the articles of food which are undergoing digestion.

Richet found that the acidity of the contents of the stomach during digestion, although it varied through considerable limits, had a marked tendency to maintain the normal average. If acid or alkali was added to the digesting mass the mean was presently restored automatically—the stomach in the former case ceasing to secrete acid, and in the latter case secreting an increasing quantity of acid.

The Effect of Gastric Juice on the Salivary and Pancreatic Ferments.

The observations of Berthelot on the power of a mineral acid to set free the acids of organic salts and to take their place with the bases—and the further observations of Richet, showing that the acids actually free in the gastric contents during digestion were organic acids, have led to the re-examination of a point of some importance—namely, as to whether the salivary, and more especially the pancreatic ferments, were or were not destroyed by the acid contents of the stomach. The matter has a practical interest in this way. If the gastric acid destroys these ferments it is evidently useless to administer pancreatic preparations by the mouth during digestion, because they would be rendered inert by the acid contents of the stomach. On the other hand, if they are not destroyed in passing through the stomach, but merely lie dormant and recover their activity in the alkaline medium of the small intestine, then we can administer pancreatic preparations during digestion with every prospect of their passing uninjured through the pylorus and proving useful in assisting digestion in the small intestine.

A series of experiments bearing on this question were submitted by T. Defresne to the Académie de Médecine and the Académie des Sciences towards the close of last year, and have attracted some attention. On the ground of these experiments Defresne arrived at the following conclusions—namely, that saliva continued its action on starch in the stomach without interruption—that the pancreatic ferments in like manner preserved their activity in the presence of the gastric acid—that the acids of the chyme, being organic acids, did not really destroy these ferments, but merely reduced them to a state of temporary inertness; so that when the acidity of the chyme was neutralised in the duodenum, they recovered their powers and exhibited undiminished activity both on starch and proteids.

As the question had a direct bearing on the medicinal administration of pancreatic preparations, and indirectly on the administration of malt-diastase and malt-extract, I thought it desirable to repeat some of Defresne's experiments and to

[1] Du Suc Gastrique, by Ch. Richet. Paris, 1878.

[2] Ann. de Chimie et de Physique, 4e Série, t. xxvi., p. 396.

Digitized by Google

put the question raised by these experiments to the test in other ways.

One of Defresne's (apparently) most convincing experiments was the following, which I give nearly in the words of the abstract of the paper published in the Proceedings of the Académie de Médecine for November 4th, 1879. When twenty grammes of dilute hydrochloric acid, having twice the acidity of the normal chyme, are mixed with twenty grammes of egg-albumen—what follows? The acidity of the medium is no longer due to free hydrochloric acid, but to the lactic and phosphoric acids of the white of egg which have been set free. In presence of these acids pancreatine may be digested for two hours in the warm chamber with impunity. And if, at the end of this period, the acidity of the mixture be neutralised, digestion is accelerated, and the pancreatine peptonises thirty-eight times its weight of albumen.

I repeated this experiment in the following manner: forty grammes of chopped boiled white of egg were mixed with forty cubic centimetres of dilute hydrochloric acid of the strength of four per thousand. This mixture was subjected to a preliminary digestion of two hours in the warm chamber at 40° C. The object of this preliminary digestion was to allow the hydrochloric acid a sufficient time to seize on the bases, and to set free the organic acids of the white of egg. At the end of this time five cubic centimetres of an active extract of pancreas were added to the mixture. A second experiment was arranged in exactly the same way, except that filtered saliva was substituted for extract of pancreas. The mixtures were kept in the warm chamber for a further period of one hour, and were then filtered and carefully neutralised. On testing the neutralised filtrates, I obtained approximately the same results as Defresne. The diastatic and proteolytic ferments of the pancreatic extract were found active, but not so active by a good deal as if the extract had been diluted to the same extent with simple water. In the second experiment with the filtered saliva the ptyalin had preserved its activity quite unimpaired.

These experiments, however, involve a fallacy which vitiates the deductions intended to be drawn from them. White of egg has a highly alkaline reaction, and although the acid used in the experiment possessed double the strength of the normal gastric juice, it was found that the mixtures, at the end of the two hours' preliminary digestion, had only a comparatively feeble acidity—in fact, only one-seventh of the normal acidity of the gastric contents. It has long been known that the salivary and pancreatic ferments are able to resist a feeble acidity, but the question really at issue is, Can these ferments resist the average acidity of the contents of the stomach, when, moreover, this acidity is rendered still more destructive to them by the presence of pepsin?

I tested the question in this way. A distinction is drawn, and rightly, between the acidity due to free hydrochloric acid, and a similar degree of acidity due to an organic acid. Now, lactic acid is a typical organic acid, and it is also an acid which is often, if not always, present in the contents of the stomach during digestion. I prepared a solution of lactic acid corresponding in saturating power to the normal gastric acid (2 per 1000 HCl.). To fifty cubic centimetres of this dilute lactic acid I added five cubic centimetres of a solution of pepsin and five cubic centimetres of an active extract of pancreas. I prepared a second similar experiment, but substituted filtered saliva for pancreatic extract. The mixtures were then placed in the warm chamber for one hour. At the end of this period the solutions were exactly neutralised and tested. They were both found to be absolutely inert. Not a vestige of amylolytic nor proteolytic power had escaped destruction.

I had an opportunity of trying the same question in a still more satisfactory way. While I was examining the throat of a patient suffering from an ailment which did not affect his general health, a portion of the contents of the stomach was ejected, and fortunately caught in a clean vessel. This was immediately filtered, and about ten cubic centimetres of clear acid solution were obtained. The period of digestion was three hours after breakfast. One-half of this was devoted to testing its saturating power. It was found to possess an acidity very nearly corresponding with that of normal chyme. To the remaining portion five drops of extract of pancreas and five drops of filtered saliva were added, and the mixture was placed in the warm chamber for one hour. At the end of this time it was exactly neutralised, and divided into two equal portions. One portion was tested with a drop of starch-mucilage, and found to be absolutely devoid of amylolytic power. The other portion was added to an equal volume of milk rendered slightly alkaline with bicarbonate of soda, and was then placed in the warm chamber. Not the slightest digestive action was produced on the milk in twelve hours.

I may mention that in the above experiments I used milk as the test of proteolytic activity. I had become thoroughly familiar with the behaviour of milk with pancreatic preparations during a long course of observations, and was therefore able to detect the slightest signs of pancreatic action.

With this evidence before me, I am unable to accept the conclusions of Defresne and others in Paris who allege that saliva and pancreatic preparations can resist the normal acidity of the stomach in full digestion; and who recommend the administration by the mouth of pancreatic preparations during the period of chymification. I will in my next lecture point out the time and the method in which these preparations may, I believe, be administered by the mouth with sure prospect of success.

Digestive Proteolysis.

The changes undergone by albuminoid substances in digestion are still very imperfectly understood. It is, however, known that the chief end-product of the transformation is peptone. It is also known that between any native proteid—egg-albumen, muscle-fibrine, casein, or legumin—and the end-product peptone there are intermediate grades and bye-products, which have hitherto proved difficult to define and isolate. The constitution of the proteid molecule is still unknown to chemists. That it is a highly-complex aggregation is certain; and it can scarcely be doubted that the way to a better knowledge of its constitution lies in a persevering study of the action on it of the digestive ferments. It has been already seen that in the case of starch the action of diastase furnished the key to the constitution of the starch molecule; and, similarly, it is not unreasonable to expect that the mystery of the proteid molecule will be finally solved by a study of the action on it of pepsin and trypsin. Attention has hitherto been too exclusively directed to peptic digestion, which is complicated by the interaction of an acid. Pancreatic digestion is, in this respect, a simpler process, inasmuch as it requires the interference neither of an acid nor an alkali, but is a reaction, pure and simple, between the ferment and the proteid. This, however, is a question of the future.

Characters of Peptones.

The end-product peptone has been fairly isolated and its characteristics defined. If the filtered product of a pancreatic digestion of egg-albumen be evaporated to dryness in a watch-glass at a temperature of 104° Fahr. (40° C.), there remains a glassy straw-coloured residue resembling dried gum. With the point of a penknife this can be chipped off in shining scales, which may be easily reduced to a fine whitish powder—this is nearly pure peptone. This substance is extremely soluble in water: and its solutions even when highly concentrated by evaporation betray no jellying, and no viscosity, but continue diffluent almost to the moment of desiccation—only just before drying up do they assume a slightly syrupy consistence. When the latter point is approached the solution deposits beautiful white crystalline sheaves of tyrosin and spheres of leucin. From the constancy with which these crystalline bodies make their appearance in pancreatic digestion it may be inferred that they constitute an essential portion of the final products of the transformation.

The reactions of peptone are mostly of a negative character. Its solutions give no precipitation with nitric acid, nor with boiling, nor with ferrocyanide of potassium and acetic acid. The behaviour of peptone with alcohol is peculiar. When a strong peptone solution is dropped into absolute alcohol, the peptone is precipitated as a white sediment, but it is not truly coagulated into an insoluble modification, as all the other proteids are, for when the alcohol is removed the deposit is found to have preserved its solubility in water—even after prolonged contact with the alcohol. Solutions of peptone are precipitated by those metallic salts which throw down other proteids, also by tannin when the solutions are neutral. When the solutions are rendered alkaline, the cupro-potassic test (Fehling's solution) added in very small quantity produces a rose-red colouration, whereas other proteids produce a violet tint. Physiologically, by far the most important reactions of peptone are its extreme

Digitized by Google

solubility in water and its diffusibility through organic membranes. With regard to the latter point, contradictory statements have been made by different investigators. Otto Funke rated the diffusibility of peptone through the membrane of the small intestine higher than that of common salt. On the other hand, V. Wittich concluded that peptones did not pass through parchment paper more rapidly than unaltered albumen. My own observations support the view that peptone is incomparably more diffusible through parchment paper than the native proteids. In the case of milk, the effect of digestion is very marked in regard to its behaviour in the dialyser. When milk was dialysed for forty-eight hours into twice its volume of water, not a trace of proteid matter could be detected in the diffusate; but when milk had been previously digested for a couple of hours with pancreatic extract, an abundant reaction with tannin and Fehling's solution was obtained after dialysing it for eight hours.

My results with egg-albumen were equally striking. I prepared a solution by agitating white of egg with nine times its bulk of water, and straining the product through muslin. When this solution was dialysed into twice its volume of water for thirty-two hours it yielded absolutely no reaction with tannin nor with the cupro-potassic test. But when the same solution was previously digested, either with pepsin and acid, or with pancreatic extract, and then dialysed, it gave in five hours a slight but distinct reaction, both with tannin and with Fehling's solution, and in sixteen hours a most abundant reaction.

The theoretical views held by physiologists in regard to the intimate nature of the transformation undergone by proteids in the presence of pepsin and trypsin are still unsettled, but recent opinions converge towards the idea that the process is, in the main, one of progressive deduplication with hydration, similar in type to the transformation of starch by diastase. This view receives a positive support from the recent analyses of Henninger. By operating on highly purified albumen, fibrin, and casein, Henninger[3] succeeded in obtaining peptones in a state of great purity. An analysis of peptones so obtained indicated that they contained less carbon and nitrogen, and proportionally more hydrogen, than their original proteids. The differences were, it is true, small, but they pointed distinctly in the direction of the conclusion that there was a fixation of the elements of water by the proteid in the course of its transformation into peptone.

Henninger also believes that he has succeeded in reversing the process, and in reproducing an albuminous substance from peptone by operating on it with dehydrating agencies. He found that when fibrin-peptone was heated with anhydrous acetic acid at 80° C., or was maintained for an hour at the temperature of 160° to 180° C., it yielded a body which agreed closely in its reactions with syntonin.

The intermediate products which are generated in the course of proteid digestion, and stand between the original proteid and the end-product peptone, are very imperfectly understood. The laborious researches of Meissner and Kühne have shown that several such intermediate bodies are produced, but these have not yet been adequately isolated and defined.

CORONERSHIP FOR WEST KENT.—A petition has been presented to the Court at the West Kent Quarter Sessions from the Dartford Local Board of Health, the document also being signed by the vicar and churchwardens of Dartford, praying that the West Kent Commissioner's district should be divided into two districts, to be called the Greenwich and the Dartford district, and that a coroner should be appointed for each district. They suggest that the Greenwich district should consist of the following parishes:—Beckenham, Bromley, Cudham, Charlton, Chislehurst, Chelsfield, Downe, Farnborough, Greenwich, Hayes, Halstead, Keston, Kidbrooke, Lee, Lewisham, Mottingham, St. Nicholas (Deptford), St. Paul, Deptford (that portion in Kent), Plumstead, Woolwich, and West Wickham. The Dartford district, they recommend, should include the parishes of Bexley, Crayford, Darenth, Dartford, Eltham, Erith, Eynsford, Farningham, Fawkham, Footscray, Hartley, Horton Kirby, Knockholt, Longfield, St. Mary Cray, St. Paul's Cray, Southfleet, Stone, Sutton-at-Hone, Swanscombe, East Wickham, and Wilmington.

ON

THE TREATMENT OF STRICTURE OF THE URETHRA, ENLARGED PROSTATE, AND STONE IN THE BLADDER,

WITH SPECIAL REFERENCE TO RECENT PROGRESS.

Delivered at the Medical Society of London, February, 1880.

BY W. F. TEEVAN, B.A., F.R.C.S.,

SURGEON TO THE WEST LONDON AND ST. PETER'S HOSPITALS.

LECTURE III.—PART I.

MR. PRESIDENT AND GENTLEMEN,—I now proceed to the consideration of the enlarged prostate. The treatment of this local nuisance continues to be much as heretofore, palliative only. Heine has attempted to cure the affection by injections of iodine; but they do not seem to have been very successful, for in several instances suppuration took place, attended once or twice by a fatal result. Atlee has recorded cases in which he obtained marked diminution in the size of the enlarged organ by the administration of ergot of rye. I have myself given the drug in large doses for months together, but I did not observe any appreciable reduction in the bulk of the gland. In France, compression, dilatation, electricity, incision and excision, have all been tried; but the only effectual measure would seem to be the excision of the obnoxious portion, as invented and practised by Mercier, whose name will for ever be associated with this subject, for his investigations into the pathology and treatment of the complaint were so exhaustive, that he left but little to be done by those who followed him. Although Guthrie had recognised "the bar at the neck of the bladder," Mercier established the very great pathological differences between the "valvule musculaire" and the "valvule prostatique." His coudée and bicoudée instruments have obtained a world-wide reputation, and his elbowed catheter is known all over his own country as "the old man's catheter." To Velpeau belongs the merit of having established the analogy which exists between fibrous tumours of the uterus and those of which prostatic outgrowths are made up. Professor Ellis showed that the prostate was not a gland, but a body composed of unstriped muscular tissue. The pathology and treatment of the enlarged prostate, as usually understood in this country, might be expressed by a knob jutting up at the entrance to the bladder, requiring a catheter shaped like a Saracen's scimitar to pass over it. A little reflection will show how imperfect and rudimentary such a conception must be. Although it is perfectly true that the median portion lying behind the verumontanum (sus-montale) is the part usually enlarged, yet it is by no means uncommon to meet with cases where either one or other of the lateral lobes is hypertrophied, thereby causing great deviation in the course of the urethra, so that the passage of a metal catheter is an impossibility.

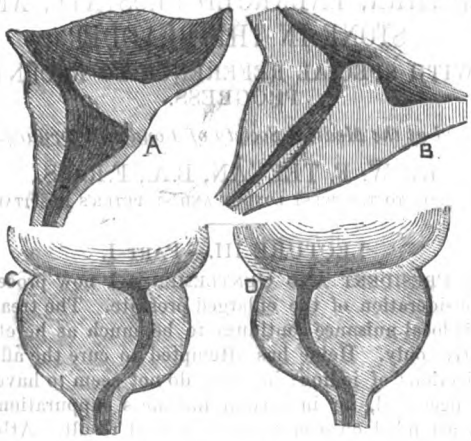
The following diagrams[1] illustrate the four separate and distinct conditions which may be found interfering with micturition. The first one (A, Fig. 9) represents "the bar at the neck of the bladder" of Guthrie, or "valvule musculaire" of Mercier, which consists of a transverse fold of mucous membrane, enclosing hypertrophied muscular fibres at the rectal aspect of the meatus internus, and differs greatly from "the valvule prostatique," B, or enlarged third lobe of the prostate, as it is commonly called, although in reality there are but two lobes. Either lateral lobe may alone be enlarged, as seen at C, where the right one may be observed greatly increased in size, pressing the urethra into a crescentic-shaped canal, and at D the left one is seen to be similarly affected, deflecting the urethra to the opposite side, rendering it impossible to introduce the ordinary metal prostatic catheter. Anyone who has had much experience in introducing silver instruments in cases of enlarged prostate

[1] Figures A and B are taken from Mercier and Phillips.

Digitized by Google

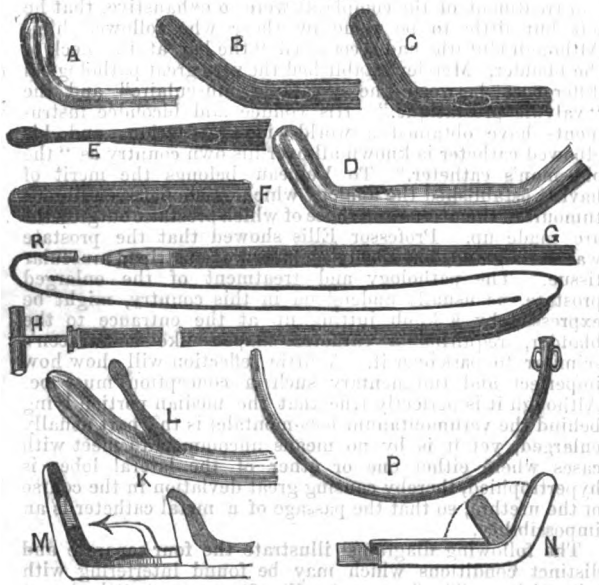
must have occasionally noticed, that in endeavouring to pass a catheter it was arrested at a certain spot, and deflected to the right or the left, so that the handle of the instrument made a quarter turn to the right or the left in the surgeon's

FIG. 9.



hand. The only instrument which can effect a diagnosis between a muscular and prostatic valve is the short-beaked sound of Mercier (see A, Fig. 10.) Its beak is the shortest ever made, and is set almost at right angles to the shaft. It might at first sight be supposed that it was difficult to introduce, but this is not so. There is no instrument so easy to pass as a short-beaked lithotrite. I have never seen a case where one or other failed to slip in, the difference of an eighth of an inch in the beak determining success or failure. Rectal examination may elucidate whether there

FIG. 10.



be general or partial enlargement of the prostate, but it will fail to discover any alteration in the central median portion behind the verumontanum. The most important object in connexion with the enlarged prostate is to choose for a patient that catheter which he can introduce with the greatest ease and the least annoyance. Till within the last few years the English gum-elastic catheter was that which was usually placed in the patient's hands. Its end had, however, to be very curved, and then set; and as it was only good for one introduction, without requiring to be again reset, gentlemen obliged to use catheters usually kept a mahogany case containing seven of them, one for each day in the week, set in grooves, and ready for use. Now, all this cumbersome appliance is done away with, and patients carry in their walking sticks, or umbrella sticks, but one catheter.

Mercier was led by his investigations to invent the coudée catheter (C, Fig. 10), which goes by the name of "the old man's catheter" in France. Such a success was it, that six weeks after its introduction Leroy d'Etiolles brought out his coudée catheter (B, Fig. 10), which was a bad imitation of Mercier's, from whose it differed only in having its beak set at a more obtuse angle to the shaft, so that it was very liable to impinge against the prostatic obstruction instead of riding over it. Mercier's catheters are made with beaks of varying lengths; the illustraton represents a long one. As a rule the shorter the beak the less will it annoy the patient. Of all catheters for prostatic use the coudée is, perhaps, the one most generally applicable. I myself prefer the olivary catheter (E, Fig. 10), but in order that it may pass easily it must have a long slender neck and well developed olive, otherwise it will impinge against the prostate, cause bleeding, and prove worse than useless. If, however, it be made as I have pointed out, its olive will usually mount the prostate, and glide into the bladder. If the catheter will not pass it can usually be made to do so by bending the last half inch at right angles to the shaft, so as to make a condée beak to it. Provided an olivary catheter suits the patient, it is by far the best one for him to use, I think, as it can be introduced very quickly and without annoyance. The india-rubber cylindrical catheter (F, Fig. 10) is that preferred by Hutchinson, Socin, and Van Buren. There is no doubt that it is the one which can be introduced with the least annoyance to the patient, but this great advantage is counterbalanced by the fact that it cannot be passed quickly, which is a great objection; for if a patient cannot introduce his instrument rapidly he becomes nervous, fidgety, and fails. In a considerable number of cases the india-rubber instrument cannot be passed; it can often be made more manageable by inserting a close-fitting bougie-stylet for about two-thirds of its length, leaving the last three inches empty, so that the very limpness of its extremity may enable it to be passed over the obstruction. If a surgeon be called in to a case of retention from enlarged prostate, he usually tries to pass the silver "prostatic catheter," but I consider it ought only be taken as a last resource; in inexperienced hands it is, to use Keyes' expression, "a murderous weapon." For the relief of prostatic retention, by whatever pathological alteration it may be caused, I know of no instrument equal to the "sonde à vis portant un conducteur" of Dr. Charles Phillips, the author of the well-known work "Maladies des Voies Urinaires." The filiform bougie (R, Fig. 10) can be wriggled over an enlarged third lobe, or round a lateral one into the bladder; the catheter, G, is then screwed on to it, and made to follow it into the bladder. The eye of the catheter is placed near the ferrule, which is objectionable, for as the instrument may be bent at right angles when traversing the subpubic region, it is liable to crack at its weaker part, which is at the eye. I have therefore had the eye made in the brass ferrule, as seen in the illustration. By this little change there is no longer any weak spot at which it may crack. There are other catheters for relieving retention from enlarged prostate. H, Fig. 10, represents an over-sliding catheter introduced by Maisonneuve. It consists of a fine olivary bougie, to which is attached a cord twelve inches long fixed to a crossbar; a catheter, open at both ends, is passed over the bougie and string till it meets the crossbar. The surgeon introduces the bougie into the bladder, and, holding the crossbar in the left hand, slides the catheter over the bougie, which is then withdrawn. Another catheter is that of Récamier (P, Fig. 10), comprising half a circle. It hugs the roof of the urethra during the entire time it is being introduced, so that it avoids the prostatic third lobe and false passage, which latter is nearly always in these cases found in the floor of the urethra in front of the obstruction. In certain cases, where there is not only a third enlarged lobe, but the general body of the prostate is considerably augmented as well, thereby causing great elongation of the prostatic urethra, Mercier's bicoudée catheter (D, Fig. 10), will be found most useful. There are also the American vertebrated catheters of Gross and Squire.

One of the most troublesome complications is the presence of a false passage, which is always, I may say, situated in the floor of the urethra. There are two different methods of overcoming the difficulty. One is to pass a medium-sized metal catheter, as suggested by Mercier, and leave it in the false passage; a small elastic catheter is then to be introduced by the side of the metal one, and as the false channel is occupied by it the elastic instrument will glide into the bladder. For effectually meeting the difficulty caused by a

Digitized by Google

false passage, Mercier invented what he called his "invaginated catheter." It consists of a full-sized metal catheter very slightly curved (see K, Fig. 10), containing an elastic catheter, L, which is turned out by means of an inclined plane, so that when the silver one has gone into the false route, the surgeon can shoot out the elastic catheter.

If no instrument can be introduced, what operation should be performed? I consider tapping the bladder through the rectum to be an objectionable procedure, for it necessitates the patient's confinement to bed with a tube up his bowel, which becomes covered with fæcal matter, and is very likely to slip out: the opening is liable to remain as a fistula, and cannot be utilised. The relief afforded by the operation is only temporary, and after the removal of the tube the patient is left in much the same condition as he was before the operation. Aspiration of the bladder above the pubes affords but transient relief. Far better is it to tap the bladder above the pubes with a full-sized trocar and cannula, through which an elastic catheter can be passed into the bladder and retained there.

In connexion with the enlarged prostate cysto-prostatitis naturally obtrudes itself. It is very common to observe a certain amount of chronic inflammation in men who are obliged to use a catheter, which might often, I think, have been avoided if the urethra had been very gradually accustomed to the introduction of the instrument. If a man begins to pass a catheter twice a day from the first, he is very likely to irritate and inflame the urethra; but if, on the other hand, he merely introduce the instrument every other day for the first fortnight, once a day for the second, and twice daily afterwards, the urethra will have time to become accustomed to the frequent intrusion. When there is much deposit of muco-pus the bladder ought to be washed out daily with warm water, for which purpose I know of no apparatus so good as the American one of Keyes. Some cases of chronic cysto-prostatitis resist every means of cure, and are in this country usually left to be broken up by pain and want of rest. In America cystotomy has been established as an operation for such patients, by Willard Parker, Emmett, Gouley, Mastin, &c., the object being to treat the bladder as a suppurating sac, and give it physiological rest by allowing the urine to dribble away as fast as it trickles in. I think that future experience will prove that the incisions of lateral lithotomy are unnecessarily severe for the purpose, which can be equally attained by external urethrotomy, with which operation I have contented myself, and allowed all the urine to run away through a soft tube. It is wonderful to see the immediate relief which such an operation affords; a patient who has perhaps been tormented for years, and has not known a good night's rest, sleeps soundly the night of the operation, having lost all his pain.

I will now for a moment glance at those patients who pass their catheters comfortably twice a day, and have nothing to complain of. Under favourable circumstances they may go on for years, and all is well; but there comes a time in the history of every such patient, if he only live long enough, when the hand loses its cunning or the sight becomes dim, and the catheter is no longer passed with the same skill and ease as of old, some hitch occurs, and the man is beaten. The aid of the nearest doctor is sought, but he very likely fails in so complicated a case. The hospital surgeon is then called in, who probably after some difficulty succeeds. The result of all the combined manœuvres too often is that cystitis or hæmorrhage carries off the patient. Then, again, there is another set of cases. A man goes on well for some time, but a period arrives when he finds that he has not long emptied his bladder with the catheter before he is again troubled by an urgent call to micturate, and has to use his instrument; the intervals of respite become less and less distant, and the unfortunate man at last finds that half an hour after he has emptied his bladder he is tormented with an urgent desire to urinate, which destroys his night's rest and makes life a burden to him. Now is the time for surgery to interfere and to try and save the unhappy patient from the doom which so surely awaits him. I consider that whenever auto-catheterism is becoming increasingly difficult or frequent, the time for action has arrived, and must not be delayed. Far better would it be if the operation were not postponed till the patient's strength be undermined, but that action were taken on the earliest indication of coming trouble. There are three different operations open for selection. 1. There is the supra-pubic puncture for the purpose of establishing a new route, allowing the urethra to fall into disuse. 2. Puncturing the urethra at the apex of the prostate, thereby giving the patient a second meatus externus. 3. The excision of the obstruction as invented and practised by Mercier. Of all these operations the last is the only one that removes the cause of the trouble; hence it is theoretically perfect in its conception. Hundreds of men now alive to whom Mercier has restored the faculty of free and natural micturition, prove that the operation is as good in execution as it is in theory. The alleged danger of hæmorrhage has not been sustained by experience, and sinks into insignificance when compared with the great results achieved. There are other French surgeons besides Mercier who have tried the operation, and reported most favourably of it; curiously enough, I believe, it has never been performed in this country. The instruments for incising the muscular valve and excising the prostatic one are respectively represented at N and M, Fig. 10. Supra-pubic puncture has its advantages and disadvantages; it is the only one of the three operations eligible in the event of the surgeon not being able to pass any instrument along the urethra into the bladder; its special risk is urinary infiltration causing peritonitis. The operation which I have been in the habit of performing is that of opening the membranous urethra just in front of the prostate, in order that the patient may have direct and easy access to his bladder. It might at first sight appear that in these cases catheterism from the perineum would offer no advantage over that manipulation s performed in the ordinary way down the penis, but this is not so. What is it that sometimes renders catheterism difficult, and at times impossible? The trouble is not directly caused by the third lobe, but the general enlargement of the prostate converting the sub-pubic curve into an angle which, if it be very "accentuated," as the French call it, may render catheterism impossible. In the normal urethra the course of its deeper portion is a gentle curve; but when the prostate is much enlarged it is greatly elongated and carried upwards and forwards, forming a sharp angle with the membranous part, which is fixed between the layers of the triangular ligament. In such cases, if an opening be made into the membranous urethra and a catheter introduced, it will glide into the bladder with the greatest ease, *as it has only to mount an inclined plane.* So easy is catheterism from the perineum that a child or nurse may perform it, and it is a painless and bloodless procedure. I have seen remarkable instances in which catheterism before the operation was painful, difficult, and bloody, but after the perineal puncture had been established it was free from all the above annoyances. A point not to be lost sight of is the more effectual drainage afforded by the perineal opening as compared with the supra-pubic. This is important, for every man who is obliged to use a catheter may be looked upon as having a reversionary interest to stone in his bladder.

ABSENCE OF PATELLAR TENDON-REFLEX IN A CASE OF PARALYSIS FOLLOWING DIPHTHERIA.

BY THOMAS BUZZARD, M.D., F.R.C.P.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

A GENTLEMAN, aged thirty-seven, applied to me on July 4th, 1879, on account of numbness in his fingers and feet. He had been in England only a fortnight, and the numbness had commenced shortly before landing in this country.

It appeared that he had left India on May 4th. Two or three weeks before his departure he complained of a soreness in his throat, which was cauterised by his medical attendant, who told him at the same time that there was a diphtheroid throat prevalent among the natives, several of whom had been in hospital under his care. The patient's throat got worse and became ulcerated, yet for about a week or ten days he continued to do duty. But he became gradually much weaker, and when put on board ship on May 4th he was not expected to live. On the voyage, however, he recovered completely, and landed in England feeling quite well, except for a feeling of numbness in his fingers, which had commenced about three weeks after the

Digitized by Google

throat had recovered. It was only since his arrival in England that the numbness had extended to his feet.

On examination I found no objective signs of disease. The patient looked well, and had no complaint to make of his general health. There was simply, he said, a little feeling of numbness in the ends of the fingers, which made it difficult to pick up small objects and button his clothes, and in the feet a similar sensation. His urine contained no albumen. The ophthalmoscope showed no change in the fundus oculi. His sight was perfectly good, and he had no difficulty in accommodation. There was no history of syphilis. The patellar tendon-reflex was normal in each leg.

On July 7th he complained of some want of power of grasp. The muscles of the forearms showed a normal reaction to induced currents.

A fortnight later (July 23rd) I saw him again. The feet and hands, he said, now felt perfectly dead. In walking he would catch his left foot. The symptoms did not affect any part of the head or trunk, but were entirely confined to the four extremities, in which there was considerable loss of cutaneous sensibility and a certain loss of power. As an illustration of the loss of sensibility in his hands, he told me that he had taken his cheroot-box out of his pocket with the full conviction that it was his purse. He had the greatest difficulty in dressing himself.

The sensibility for temperature was to a great extent retained, and he could tell the difference between a linen and a woollen material, not by the texture, but by its power of conducting heat. There was, however, some delay in the appreciation of heat impressions. He told me, for example, that he had to leave his hand in water a few seconds before he could be sure that it was of a proper temperature to use to his face.

He was weak on his legs, so that walking made him feel tired and sick, and he could not go downstairs without keeping hold of the balustrade. I noticed now that he staggered a little in his walk, and when he stood with his feet together, and the eyes were closed, he swayed about. The numbness was described as having now extended up the back of both legs.

I could find no very notable defect of electrical excitability in the muscles of the forearms, but the response in each was alike, and it is not easy therefore to be sure on this point. Examination of the urine, as well as by the ophthalmoscope, continued to give negative results. There was no difficulty in swallowing, the sight was still unimpaired, and the functions of the bladder and rectum remained normal. The patient looked well, and said that he felt perfectly well, except in respect of the symptoms described. The patellar tendon-reflex was now found to be absent from both legs.

After this I lost sight of the patient, who was living at some distance from town, until a few days since. He tells me that he quite recovered about the end of August—i.e., in about a month after his last visit. Examination now showed the patellar tendon-reflex present and normal in each leg.

The treatment consisted in the use of faradaism, and the administration of iron and arsenic.

There was a complete absence in this case of many symptoms which are so commonly present as to be almost pathognomonic of diphtherial paralysis. The voice had never acquired any nasal tone, nor was there any difficulty in swallowing, and fluids never regurgitated. The sight remained throughout perfectly good, the smallest type being able to be read at a normal distance, so that the accommodation of the eyes, which rarely escapes in the paralysis following diphtheria, was never in this instance affected. The numbness described was confined to the extremities, no part of the head or trunk being the seat of it at any time.

The disappearance of the patellar tendon-reflex whilst the patient was under observation, is interesting. It furnishes proof, if such were wanting, that this peculiar paralysis is dependent, when it affects the extremities, upon a lesion either of the spinal nerves or in the substance of the cord. A cerebral lesion would not account for this symptom. A lesion of the posterior roots of spinal nerves alone would be sufficient to interrupt the reflex; but the fact that there was loss of power as well as anæsthesia, shows that, if the lesion were not one of the substance of the cord, it must have involved either the trunks of the mixed nerves or the anterior as well as the posterior roots.

Grosvenor-street.

ON

POLYPUS AND OTHER MORBID GROWTHS IN THE NOSE:

THEIR RADICAL TREATMENT BY THE ELECTRO-CAUSTIC METHOD, AND THEIR CONNEXION WITH ASTHMA.[1]

BY J. L. W. THUDICHUM, M.D., F.R.C.P.L.

IT is my intention to bring under the notice of the medical profession, in as brief a form as possible, some general results concerning the treatment of polypus and other morbid growths in the nose, derived from practical experience extending over more than 300 cases. While in the early days of my practice I operated with the forceps like everybody else, and even had some permanent successes with it, I became convinced about sixteen years ago that this instrument had to be abandoned, and I substituted the electro-caustic platinum-wire noose for it. My first publication on this subject was made in THE LANCET fourteen years ago. My further experience was published in an essay, of which the third edition was published in 1877 by Messrs. Longmans.

The immediate objections to the use of the forceps are that it causes great pain on mere introduction, and the view into the nostril is immediately closed. It is then next to impossible to open the blades sufficiently to grasp more than a thin end; in the best case the stalk of an anterior polypus. Consequently the rest of the polypi are pushed backwards or upwards in the nose, and jammed into the narrow recesses of the upper nose. At the same time there is bruising of the mucous membrane over the ascending ramus of the upper maxillary bone, and bruising and tearing of the Schneiderian membrane of the turbinated bone and septum. Then there follows much bleeding, secondarily ulceration, and, in some cases, gangrenous destruction of ill-treated parts. But worst of all is the inefficiency of the result. If a passage is produced it frequently only lasts for a few days, and soon the nose is closed again. Only few cases of simple form—e.g., in young women—are freed and permanently cured.

Worse than these immediate evils are *the permanent evil results of forceps operations*. In some cases I have observed amongst such results, closure, partial or entire, of the nostril (atresia). In two cases, one male, the other female, the closure was complete; in another case there remained only a small opening through the membranous formation sufficient to admit a probe. In a greater number of cases the injury to the surface of the nasal cavity causes membranous adhesions between the turbinated bones and the septum. When the forceps is used by strong hands, a good deal of tearing and breaking of the turbinated bones is effected, ending in their dislocation. This disorder then heals up, and causes great discomfort. In such a case the lower turbinated bone lay against the septum and caused constant pain. I removed it entirely, and the patient was quite restored, the pain ceasing immediately. In quite a number of cases the forceps produces fracture of either the cartilaginous or bony septum. In two such cases, one from the antipodes, another from a northern county, there was a history of hæmorrhage, in consequence of which the operation was left uncompleted and the nose plugged; then followed gangrene of part of the septum, with perforation and loss of substance. These illustrations suffice to explain the preference for my new method expressed by all patients who have experienced the forceps.

The electro-caustic method of operating on nasal polypus I was the first to use. Even Middledorpf, the inventor of the electro-caustic method of operating, did not operate for nasal polypus; an illustrious member of our profession, being himself afflicted with polypus, visited Middledorpf for the purpose, as he hoped, of being operated upon by electro-cautery; but he was disappointed, and operated upon with the forceps.

The advantages of my new method over all former methods are that it is greatly superior in results; that there is no, or

[1] A paper read before the Medical Society of London on March 16th, 1880.

Digitized by Google

next to no pain on introduction of tools; that the tools are so thin that even when two or three are simultaneously used, there is yet room by their side for completely illuminating at least that part of the cavity of the nose in which it is desired to operate, and thus avoiding doing anything in the dark. The method allows freedom to the operator to shift his and the patient's position. Pain and bleeding are limited to a minimum, and the results as to the restoration of freedom of respiration through the nose are simply perfect. This method further removes all necessity to operate, for polypi, through mouth and pharynx. I have had a number of cases, from which some polypi had been elsewhere removed through the mouth from the choanæ, after numerous sittings and great torture to the patients; and yet the patients had the posterior nares filled with polypi. These cases were completely freed by my method, applied exclusively through the anterior nares. I bring the posterior polypi forward by easy traction, effected by suitable tools—blunt hooks, sharp hooks, either of steel or flexible metal, sliding hooks, fine forceps appropriately bent, and all so thin as to pass the narrowest nostril. The description which some authors have given of my method, in saying, e.g., that I used no traction, is therefore quite contrary to fact.

The mode of rhinoscopy which I have described has also been confirmed as simply perfect. The use of *choanoscopy* (erroneously called posterior rhinoscopy), is useful for diagnosis, but not for operating except in very few cases. My method of rhinoscopy (by some unnecessarily termed anterior rhinoscopy), by means of the blade specula, with spring lever attached and without any screws, has met all wants of practice. All screw specula are slow and inefficient, and I have not the slightest doubt that Voltolini's screw specula and Zaufal's internal tube specula must be rejected, as well as their methods. Indeed, Zaufal's nasal tubes or specula for seeing through the nose into the pharynx or posterior nares are quite unnecessary; moreover, they are mischievous by causing pain, and frequently hæmorrhage, sufficient at all events to entirely destroy the objects of the introduction. Compression of the spongy layer of the turbinated bone with a probe or blade is very useful; the spongy tissue yields, and a canal is produced where there was none, or the existing canal is made wider. For this purpose the laminaria is also useful, but its application requires much skill and patience.

The broad hook for drawing the soft palate forward in choanoscopy, lately recommended by Voltolini as a novelty, I have used since 1864; it is perfectly correct that a strong traction upon the soft palate is preferable to a slight one, because much better borne by the patient.

Operations by electro-cautery for the ablation of excrescences in the nose other than polypi—namely, fibrous, adenoid, osseous, or osteo-cartilaginous growths—are very successful. *Atresia*, or *closed nostril*, is opened by proceeding with the electro-caustic wire from without inward. After the cavity has been opened the projecting parts are further excised until sufficient space is produced to effect contraction in healing.

Ablation of the turbinated bone, an important operation, is effected in two stages; one act is the cutting away of the cavernous tissue with the white-hot wire; the other, the cutting away of the bone with nippers, or chisel and hammer. In most cases the removal of a short piece, of an inch, at most an inch and a half in length, suffices to establish a good canal. Polypi frequently have *bony excrescences* in their substance, which have to be similarly removed, and to be carefully manipulated to prevent wounding the nose by their sharp edges.

Adenoid tumours of the pharyngeal cavity, which alter voice, expression of face, hearing, and cause the patients to snore greatly during sleep, can mostly be detached by seizing them at the base with the sliding hook, and twisting away as for stopping a bleeding artery by twisting, until the hook comes out. By repeating this process the tumour is at last detached clean. Care must be taken to fix it through the mouth by some means, when it becomes visible, to prevent its falling into the pharynx and larynx. I have had cases in which danger was averted only by rapid action. If the tumour were swallowed the operation would lack its *corpus delicti*, which is unsatisfactory. I have cut off one such adenoid tumour by passing the loop through the one nostril until it touched the posterior wall of the pharynx; the tumour was manipulated through the other nostril; when cut off, it was drawn through the nose, and required great force to get it to pass. The case was perfectly successful, and the result important, as the subject was a clergyman.

Epithelioma of the nasal cavity is a peculiar form, and must be treated cautiously. It is always very soft, and in later stages gives rise to great hæmorrhage when touched. In this way it also terminates fatally by spontaneous bleeding. I have seen a case of such epithelioma complicated with common polypus.

Concealed abscesses in the nasal cavity give rise to much trouble. In the anterior part of the septum they exist as results of injury, such as occurs from boxing, falling, from blows by cricket-balls or swung-gates. The size which the septum can acquire in such cases is enormous. In such cases I fix a drainage-tube at the lowest point; the tube is kept in position by platinum-wire fixed on the outside of the nose by adhesive plaster. Dead bone is carefully searched for and removed, with nippers in pieces if large. Such dead bone is sometimes buried deep in thickened tissue, and is discovered only after the diseased tissue is cut away by the electro-cautery.

Abscess complicated with a small aneurism, I met with once on the septum of a medical colleague. In opening the abscess the aneurism also was opened, and I had much to do to stop the bleeding by the electro-cautery. This is the only case in which I have seen blood welling out of any part of the septum. In most cases of injury or disease the septum only oozes out blood.

Fibro-cartilaginous tumours occur on the septum in children and young persons. They are to be treated like bone if the passage is obstructed. If they are small I advise not to touch them.

The pernicious *fibrous*, *osteo-fibrous*, or *osteo-cartilaginous tumours*, which arise from the roof of the pharynx, and occur only in persons below the age of twenty-five years, are very rare, and their operation demands the greatest circumspection on account of the appalling hæmorrhage which is liable to arise in the course of it. If in such a case the tumour has advanced to the anterior nose, I should recommend the removal of the septum, and digging out of the tumour through the nose by means of the electro-caustic spoon.

Foreign bodies in the nose cause chronic diseases of the ozæna type. I operated upon a boy, supposed to have dead bone in his nose, who had a shoe-button firmly imbedded in a cavity of the cartilaginous septum.

Operation for polypus in cases where both nostrils are completely obstructed, disfigured, narrow, and distorted, has to be carried on by instruments guided by the feeling, without the aid of the eye. A lady, who had been, so to say, quite demoralised with long-standing disease, was so cured. She took the mucus from the nostrils with an ivory spoon, being quite unable to blow either nostril; was emaciated and much distressed. She insisted on the use of chloroform, under which, however, the operation could not be made. With much trouble she was persuaded to sit quiet and be operated upon without the anæsthetic. She gained confidence by little successes, and became so far restored by the removal of many polypi, none of which was ever seen previous to extraction, that she could blow her nose and inspire as well as expire through it. She would not consent to have an operation for widening the nasal canal performed upon her.

The *hearing* is affected in many cases, particularly of polypus, but also of chronic affection of the Schneiderian membrane, either on one side only, or on both sides; the patients are hard of hearing or deaf. They frequently recover immediately on removal of the choanal polypi; great is sometimes the astonishment, always the joy, of these poor people. It is, in the first instance, pressure on the choanal end of the Eustachian tube which disarranges, ultimately disorganises, the inner ear. The outer ear must be carefully examined in such cases.

According to my experience a considerable number of persons are thrown out of career, employment, or situation by diseases of the nose. Clergymen, barristers, military and naval officers, merchants, medical men, and farmers are most severely afflicted when polypi interfere with their speaking power. *The causes of polypi* frequently cannot be traced; they occur in well-made and otherwise healthy young women, and in these do not relapse when once removed. They sometimes develop during pregnancy. In one such case I have known the cystic polypus to burst, then to atrophy and require no removal. In the greatest number of cases, however, some dyscrasia or other, acquired or inherited, is the cause of the evil. Scrofula produces more frequently thickening and ulceration, and the bad forms of ozæna, than polypus.

Digitized by Google

Among the *complications of nose diseases*, particularly polypus, none is more common than *asthma*. About every fifth case of chronic nose disease has or has had asthma, continuously or at periods. Frequently this asthma disappears after removal of the polypi, even when they are very small. Some patients were so sensitive to irritation in the nose that they were seized with an attack of asthma when the cavity of the nose was touched by instruments. I have seen the most curious varieties of nose disease complicate asthma, even a red thickening of the outer nose, in very abstemious, regularly-living persons in good society. In strong men of active habits the presence of polypi in the nose leads to chronic congestion of the posterior parts of the lungs, for which there is frequently no relief except the complete removal of the nasal polypi.

The asthma is sometimes relieved by the careful use of ammonic chloride and potassic iodide. But the iodide must not be used when there is bronchitic complication. Here the most useful remedy is the inhalation of the pyrolytic vapours of extract of opium, of belladonna, of Indian hemp, of hemlock, of hyoscyamus, of stramonium. All these remedies have been used for a long time in one form or another, though not in the form here alluded to. Most patients of both sexes who came under my observation had smoked stramonium leaves, or some little rolls of blotting-paper in which a vestige of the solid contents of the tincture of these substance was contained. Some used preparations of vegetals impregnated with nitre and ammonic chloride. These powders are burnt on a tray, and the smoke is inhaled. It contains ammonic carbonate arising from the double decomposition of the potassic carbonate formed from the nitre with the ammonic chloride. These mixtures are called "cures," but seem to me to be destitute of any real alterative or symptom-relieving power.

The asthma accompanying nasal polypus may be inherited by the offspring without the polypus, just as polypus alone is sometimes inherited. Of the former I observed a remarkable case some years ago. A strong man following an open-air trade, had been suffering from gout and polypus, and intermittently from asthma for twenty years. I removed the polypus, and by medical treatment much improved the patient's general condition. I was thereupon called to see his two daughters, who both suffered from periodical asthma. In the case of the elder one the attack came on every fortnight or every twenty-eight days, and lasted from one to three days. It was bronchial spasm, causing noisy, heavy inspiration; the face was livid, and the pulse vacillating between fulness and collapse; the patient could hardly speak a word; lips and tongue were dry, cracked, and fissured. Strong doses of morphia alone relieved the disorder, and reduced its dimensions and duration, if taken as soon as the premonitions appeared. The asthma was subdued by a long course of quinine and potassic iodide. The younger sister had a spasmodic panting, resembling certain hysterical forms of that neurosis. Its attacks were less regular and shorter than those in the former case, and yielded to the same remedies. I have known polypus affecting three successive generations; in one instance, seven members of one family, of whom I treated three, were said to be affected by it.

Pembroke-gardens.

THE DIAGNOSIS OF TUMOURS OF THE CEREBELLUM.

BY STEPHEN MACKENZIE, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN TO, AND LECTURER ON PATHOLOGY AT, THE LONDON HOSPITAL.

(Concluded from p. 559.)

ENLARGEMENT of the head takes place only in children whose cranial bones are not ossified. Their yielding sutures allow the collection of a great deal of fluid, and the attainment of large dimensions by the tumour. Similar enlargement may be produced by voluminous tumours—as hydatid—of the cerebrum. The enlargement is then not always so symmetrical, and is more frequently associated with hemiplegia.

When the various symptoms I have described are present we may diagnose with confidence—as was done in the three cases above—tumour of the cerebellum, but it must not be understood that with tumour of the cerebellum these symptoms are always present. I have seen cases of cerebellar tumour without these localising symptoms, and in their absence exact diagnosis is impossible.

In the present state of our knowledge it is impossible to fix the exact position in the cerebellum occupied by a tumour. A few years ago the same might be said regarding the cerebrum. Detailed reports of post-mortem examinations, and careful clinical records of cases of cerebellar tumour are required, in order that the cerebellum may be mapped out as is being done with the cerebrum. It is as a contribution in this direction that I offer these cases.

As regards the *nature* of tumours of the cerebellum the means at our disposal for its determination are very limited. The cerebellum is a rather favourite seat of tubercular or scrofulous cheesy tumours. Children are most liable to this form of growth, and there is always a strong probability of the tumour being of this character in the young. This probability amounts almost to a certainty when we have, either in the child or the adult, signs of scrofula present. In Case 3 the diagnosis as to the position and nature was complete, and in several other cases it has been equally correct. Almost any kind of tumour may occur—glioma, psammoma from the membranes, &c.,—but syphilomata in this position I believe to be rare.

Though my subject is the diagnosis of tumours of the cerebellum, I may be allowed to add a few remarks on the physiological importance and significance of cerebellar lesions. "The functions of the cerebellum form one of the most obscure and disputed questions in cerebral physiology," says one who has done much to clear up the obscurity.[1] Dr. Ferrier, in his valuable work, has given details regarding his own, Flourens', Hitzig's, and other experimenters' investigations into the functions of the cerebellum. Drawing attention to the importance of, and at the same time pointing out the difficulties in, distinguishing between the effects of irritative and destructive lesions, he says, "When the cerebellum is divided exactly in the median line in an antero-posterior direction, it is found that the disturbances of equilibrium, if any, are of no marked importance, and there is none of the tendency to reeling or rotation which characterises undefined lesion of the organ. It is also found that when lesions which are as nearly as possible symmetrical on both sides are made, that the disorders of equilibrium are also comparatively slight." In the *Medical Mirror*, Sept. 1st, 1869, Dr. Hughlings Jackson records a case in which there were, fourteen days before death at any rate, no symptoms referable to the cerebellum, although there was a tumour in each lateral lobe. There was paralysis of one arm owing to tumour of the hinder part of the uppermost frontal convolution. Dr. Ferrier goes on to say: "When the lesions, however, are established unsymmetrically, or unilaterally, disorders of equilibrium are more manifest, and the equilibrium is overthrown in different directions, according to the position of the lesion. When the anterior part of the middle lobe of the cerebellum is injured, the animal tends to fall forward, and in its attempts at locomotion usually stumbles or falls on its face (Flourens, Renzi). When the posterior part of the median lobe of the cerebellum is injured, the head is drawn backwards, and there is a continual tendency to fall backwards on attempts at locomotion. This fact I have determined by careful experiment on a monkey."

In connexion with these disturbances of equilibrium consequent on lesions of the cerebellum, it has been noted that temporary or permanent deviation of the optic axes occurs, or some degree of nystagmus or oscillation of the eyeballs. Thus Ferrier has shown that irritation of the middle lobe produces simultaneously movements of the eyeballs and head, and sometimes of the extremities also—just what is observed in the tonic convulsions associated with cerebellar disease.

Ferrier regards the cerebellum as a complex arrangement of individually-differentiated centres, which in associated action regulate the various muscular adjustments necessary to maintain the equilibrium of the body; each tendency to the displacement of the equilibrium round a horizontal, vertical, or intermediate axis acting as a stimulus to the special centre which calls into play the antagonistic or compensatory action. Thus *irritation* of the anterior part of the middle lobe produces backward movement of the head and

[1] Ferrier: Functions of the Brain. 1876.

Digitized by Google

extension of the trunk and limbs, together with upward movements of the eyes—actions which are to be regarded as natural compensatory efforts to counteract a seeming rotation forward on a horizontal axis; whilst *destruction* of the same part causes a tendency to fall backward. "In this latter we see," says Ferrier, "both the negative effect caused by the removal of the one centre, and the positive effect exerted by the unopposed and antagonistic centres."

The conditions may be compared to a driven horse. The horse is kept straight by the rein of each side held equally tight; when one rein is let go the horse turns to the opposite side by the negative effect of the slackened rein of one side, and the positive and unantagonised effect of the unloosened rein of the other side. Imagine a rein in front and behind, one for each side, and various other pairs in intermediate positions, the horse will be kept straight by a balance of antagonism of the several reins. Any slackening of one or more reins will be met by the combined action of the remaining unslackened reins. It will also be observed that the effects of discharging and destructive lesions may be the same; thus pulling hard on the right rein and slackening of the left rein will equally turn the horse to the right. The lesions of disease are less exact than the electrode of experimenters. So far as my observations go, we only have backward movements (retraction of head and extension of spine), with extension of legs and rigidity of arms, accompanied by movements of the eyeballs, whether the lesion of the cerebellum is irritative or destructive, or whatever part of the middle lobe is affected. Ferrier believes that cerebellar co-ordination is independent of consciousness or volition, yet in the normal state cerebellar activity is associated with that of the hemispheres, so that lesions of the cerebellum, whilst interfering with the mechanical adjustments against disturbance of the bodily equilibrium, do not cause paralysis of voluntary movements of muscles which are concerned in these actions. The facts stated by Ferrier on this point are in accordance with clinical observation—at least as regards movements of the extremities. Any directly paralytic affection of the extremities is due to pressure on the parts adjacent to the cerebellum[2]—pons and medulla—as pointed out by Vulpian, and as well illustrated by my second case. Otherwise destructive lesions of the cerebellum do not cause hemiplegia or paraplegia. Ferrier believes that the loss of reflex adjustment may be in time compensated for by an acquired power of voluntary adaptation, and thus he reconciles the facts of persistence of equilibration in an animal whose cerebellum has been removed, or in a human being when the cerebellum has undergone degeneration from a slowly progressive lesion. It will be seen Ferrier attributes the tonic convulsions and permanent rigidity noted in cerebellar lesions solely to *cerebellar* influence; the negative condition to paralysis of the parts governing the movements in one direction, the positive condition to the unantagonised parts governing movements in the reverse direction.

Dr. Hughlings Jackson has treated of the physiological bearings of cerebellar disease in various places. He believes that "in health the whole of the muscles of the body are doubly innervated—innervated both by the cerebrum and cerebellum; there being a co-operation of antagonism betwixt the two great centres. Whilst the cerebrum innervates the muscles in the order of their action from the most voluntary movements (limbs) to the most automatic (trunk), the cerebellum innervates them in the opposite order. This is also supposed to be the order of their degree of influence on parts; and is equivalent to saying that the cerebellum is the centre for continuous movements, and the cerebrum for changing movements."[3] In disease this co-operation of antagonism is interfered with, and the influence of one centre being removed, the unantagonised influence of the other centre is permitted. Thus in hemiplegia of some standing there often follows rigidity of the paralysed muscles. The paralysis Dr. Hughlings Jackson would ascribe to a lesion of the cerebrum, the rigidity to unopposed cerebellar influx; for, as he lucidly points out, whilst the primary cerebral lesion can account for the paralytic element—the negative condition, it cannot (nor can the sclerosis in the lateral column) account for the tonic contraction of the muscles—the positive condition. In destructive lesions of the cerebellum he would ascribe the weakness of the locomotory organs to loss of cerebellar innervation over the trunk muscles, and the rigidity to unopposed cerebral influx. Hemiplegia is analogous to paresis of the spinal muscles; hemiplegic rigidity to cerebellar rigidity. It may be mentioned that he adopts a similar explanation for the motor symptoms of Parkinson's disease (paralysis agitans). In this case a partial removal of cerebral influence permits that approach to tonic contractions which is seen in rhythmical tremor of the hands; on complete removal there is tonic contraction: in the spinal, and some other muscles there is rigidity without prior tremor, these being the parts the cerebellum in health influences most. In advanced cases there is universal rigidity and an attitude, he says, somewhat like that of a weak person going upstairs; the attitude in the rigidity of cerebellar disease is a great exaggeration of that of a person going downstairs. Much has, he thinks, yet to be done in comparing and contrasting the rigidity which certainly occurs with cerebral disease, and that which, quite as certainly, sometimes occurs with cerebellar disease. Tetanus, which is so closely simulated by cerebellar disease, Dr. Hughlings Jackson would ascribe to discharge of some part of the cerebellum. There is, he thinks, a cerebellar rigidity analogous to hemiplegic rigidity, and a cerebellar convulsion analogous to cerebral convulsion. This view as to the two kinds of convulsive seizures was first stated in his report of a case of tumour of the middle lobe of the cerebellum, in the *British Medical Journal*, Nov. 4th, 1871, where a rough comparison and contrast is made betwixt tetanus and cerebral convulsion. In the *Medical Times*, Oct. 26th, 1878, he institutes a more elaborate comparison and contrast betwixt tetanus and cerebral convulsion beginning unilaterally. In recording a case of choreal movements and of "cerebellar rigidity" in the *British Medical Journal*, May 15th, 1875, he writes: "In some cases of disease of the middle lobe of the cerebellum, the patient lies on his back with his legs and feet extended, the latter a little turned in; the arm is acutely flexed at the elbow, the wrist is flexed, and the palm is turned towards the front of the upper arm. The head may be thrown back." The case was one of tubercular meningitis. The hypothesis of Dr. Hughlings Jackson is of the highest importance, including as it does a physiological principle of wide application. There are, I feel bound to point out, a few practical difficulties to accepting this hypothesis *in toto*, but I am quite prepared to have them met by Dr. Hughlings Jackson when stated. In the first place he has pointed out as the difference between cerebral and cerebellar innervation, that from the former we have changing movements, or, borrowing, with him, medical terms to describe physiological conditions, clonic movements; whilst from the latter we have continuous, confluent, or tonic movements. Now, on removal of cerebral influx (as in hemiplegia with rigidity) there follows, according to him, tonic contraction from unopposed cerebellar innervation, and in destructive lesions of the cerebellum (as extensive tumours) we have tonic contraction from unopposed cerebral innervation. It seems to me, admitting his differences in character between cerebral and cerebellar innervation, that the effects of removal of the control of either is too much alike in kind. Again, the effect of discharging and destroying lesions of the cerebellum is too much alike, for in tetanus (discharging lesion) and in large cerebellar tumours (destructive lesion) we have alike tonic contraction of wide range; in the one from increased cerebellar discharge, in the other from removal of cerebellar influence. Nowhere else do we see such like effects from irritation and destruction of nervous centres. Irritate the cerebral cortex and movements are produced; destroy it, and paralysis follows. Next, if in hemiplegia the rigidity which sometimes supervenes is due to unantagonised cerebellar influence, how is it that it takes so long to come into play? why does it not appear as soon as the cerebral influx is removed? Dr. Hughlings Jackson tells me that he cannot explain this, and admits that his hypothesis is not, as yet, defensible all round. To what does Dr. Hughlings Jackson attribute the rigidity of the hemiplegic limbs coming on rapidly when a hæmorrhage of the corpus striatum breaks through into the lateral ventricle? Whilst I point out these difficulties I must state that my clinical experience is quite in accordance with that of Dr. Hughlings Jackson. I have seen some tonic contraction from subtentorial meningitis and small superficial cerebellar

[2] In the Medical Times and Gazette, Jan. 17th, 1865, Dr. Hughlings Jackson records a case of tumour of the cerebellum which had compressed the pons and crus cerebelli. He attributed the patient's irregular gait to pressure on these parts; he did not then believe that lesions of the cerebellum alone produced inco-ordination of movements. He believes that tumour pressing on the crus cerebelli produces some paralysis on the same side of the body, as Brown-Séquard long ago asserted.

tumours, and from destructive lesions, such as large cerebellar tumours and hæmorrhage into the cerebellum.

Finsbury-square.

CASE OF ECTROPION TREATED BY A NASO-BUCCAL FLAP; AND OTHER CASES.[1]

BY SIMEON SNELL,

OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY.

THE usual places from which flaps are taken in plastic operations on the eyelids are the forehead and temple or the upper part of the face, but the case I am about to relate was an exceptional one, and required that the portion transplanted should be derived from a different locality.

J. W. O——, sixteen years of age, is a subject of epilepsy, and on October 2nd, 1877, during a fit, he fell into the fire and severely burnt the left side of his face and head. The same day he was admitted into the Sheffield General Infirmary under the care of my colleague Mr. Barber. He made a good recovery, except that the left upper eyelid remained completely everted; and in March, 1878, Mr. Barber kindly transferred the case to me for further treatment.

His condition at the time mentioned was as follows. The left upper eyelid was altogether turned inside out, and the ciliary margin of it was drawn close up to the eyebrow and firmly cicatrised; the conjunctiva thus displayed on the inner surface of the lid was red, granular, and much thickened; the cornea was exposed, and there was no power of closing the eye. As a result of this want of protection there was some general conjunctival irritation. To obviate this and to shield the unsightliness of the eye he was compelled to cover it with a "shade." The skin also over the forehead and towards the left temple was extensively cicatrised, and on the brow near the orbital margin was a firm cicatricial band.

The boy's appearance was certainly revolting, and naturally he was desirous for something to be done to render it less evidently so. The eye was, moreover, suffering somewhat from exposure, and seemed almost to necessitate interference. The scarred condition of the tissues in the localities generally selected for taking a flap from in such cases presented a difficulty, as it appeared more than doubtful whether skin in such a state, when transplanted, would maintain its vitality. It was evident, also, that when the lid was replaced in its normal position, the gap resulting would be considerable, and the flap necessary to fill it be large.

Whilst bearing these facts in mind, and considering what would under the circumstances be the best procedure to adopt, the published Transactions of the last International Ophthalmological Congress were forwarded to me. Here I found a description of the use in two cases of a naso-buccal flap by Noyes of New York. In neither of these cases "could the usual proceedings be employed, because there was no tissue in the usual localities which could be utilised." He further pointed out that it was possible to obtain a flap fully three inches in length from the side of the nose and cheek, which would be capable of maintaining its vitality by a rich blood-supply derived from the vessels coming out of the orbit, and more on the face from the free inosculations between the terminal branches of the facial with the nasal artery. It was thus evident that a flap large enough for my purpose, and able to preserve its vitality, could be procured from the naso-buccal region. I decided, therefore, to adopt this plan, and accordingly, on March 25th, 1878, the operation was performed.

Chloroform having been administered, an incision was made through the cicatrix binding the everted lid to the eyebrow, and the tissues carefully divided until the eyelid was able to be replaced in its normal position. Next, with the object of shortening the palpebral fissure, the opposed surfaces of the lids, at the external commissure, were pared and the incisions continued outwards, so as to remove a > piece of integument from the commissure itself. The edges were then drawn together by sutures, which had the effect also of keeping the lid *in situ*, but, to still further insure this latter object, the margins of the lids were vivified at two points, and were here united by fine sutures to cause their temporary adherence. With the eyelid thus placed again in its normal position, a large raw surface was the consequence, measuring fully two inches in length and one inch in width. To obtain integument sufficient to fill this big gap, it was necessary to mark out a flap considerably larger, to allow for shrinking after dissection. An incision was now carried obliquely downwards, from the inner and lower margin of the raw surface on the upper eyelid, over the face to just below the level of the mouth, and rather more than two inches from the margin of that orifice. It was then rounded and carried back again over the nose at some little distance from its root. The pedicle was thus a little narrower than the flap was in the rest of its extent. The flap thus marked out was dissected up, care being taken to leave all the vessels as far as possible uninjured, especially at the inner orbital angle. As at first mapped out, the flap had measured three inches in length by about one and a half in width. It was now found to readily fill the rawed surface, and this without twisting. It was secured with sutures with no apparent sign of tension. The thickness of the skin, with its subcutaneous fat, occasioned a prominent and somewhat ugly appearance. It may be mentioned that the facial vein disclosed whilst raising the flap had been carefully dissected from it. Attention was now directed to the large and gaping wound left on the face by the removal of the transplanted flap. The edges were drawn together by three hare-lip pins, sutures being also placed where necessary. In this manner the wound was tolerably readily closed, and it was found to be quite unnecessary to follow Noyes in his practice of rendering the closure of the gap more easy by carrying an incision from the original wound below the lower eyelid and along the zygoma, and dissecting up the cheek thus included in these incisions. The operation was thus completed and water-dressings were applied. The time occupied was one hour and a quarter, and though this may seem considerable, the operation is necessarily a tedious one, and there is a great deal to be done. Noyes was engaged two hours in each of his cases.

The next day a little duskiness showed itself at the extreme edge of the flap at its outer side. On March 27th the sloughing had in no way extended, and appeared only superficial. The pins were removed on the third day from the facial wound, which was doing well. The sutures joining the opposed surfaces of the lids to each other gave way without producing the temporary adhesion that was desired. Granulation set in at the margins of the flap. The patient rapidly recovered, and in a few weeks left the infirmary. The flap had, however, dropped somewhat at the pedicle end, and had not become attached, as one wished, to the ciliary margin, but had fallen over and become fastened to the upper part of

[1] Read before the Sheffield Medico-Chirurgical Society.

Digitized by Google

the wound on the cheek. An attempt was made to rectify this as soon almost as it was detected, but not very successfully. The parts were given time to quietly settle down, and on Aug. 5th, 1878—the boy being again an in-patient—the inner part of the lower edge of the flap was dissected up and accurately joined to the margin of the upper lid; the edges of this part of the wound on the face being also closed by sutures. At the same time, the new eyelid seeming too bulky, the opportunity was taken of removing a small portion at the pedicle end where it was dissected up. In this way the flap transplanted on the lid was intentionally surrounded by cicatrix, with the idea, founded on a theory suggested by Mr. Teale some years since, that atrophy is induced by cicatrix, and that thus the new eyelid, which was still too prominent, would become less so. Suffice it to say this hope has been realised. I need not mention further particulars. The boy now possesses a good lid, his eye is covered, his appearance is changed, for he is now well looking. The scar on the cheek is not very noticeable, and becomes less marked. I should add, the palpebral fissure was on December 30th, 1878, brought back to its usual length by separating the lids at the external commissure.

The engravings are from photographs taken before and after the operation—the latter in October last; and in this the artist has drawn the scar on the cheek more distinct than it should be.

The operation which I have thus described does not appear to have obtained a recognised place. Noyes says he found no mention of it in the regular text-books, but supposes cases have occurred in which surgeons have employed it without having called special attention to it. Of its service, however, in certain cases there can, I think, be little doubt. In the one just related the condition of integument on the forehead and temple prevented me taking a flap from either of those regions; had it indeed been taken from the latter the cicatricial band at the inner side of the brow was where its pedicle would have been situated. In such cases, where the simpler procedures are rendered impracticable, it may be used with advantage.

I refer now to other cases, merely because they illustrate the older and simpler methods of treating ectropion. I will do so briefly.

John T. J——, about twenty years of age, suffered in childhood from an abscess beneath the right eye, evidently connected with bone. As a consequence the lower lid at its outer part had become much everted, the conjunctiva being exposed and thickened. The deformity was great, and in April, 1877, he placed himself under my care at the Sheffield General Infirmary for its relief. On April 27th he was placed under chloroform. A short space below the everted margin of lid was a depressed cicatrix, firmly adherent to a bony nodule. A little distance on either side of this two converging incisions were carried, commencing immediately beneath the ciliary margin, and uniting just below the cicatrix. The V-shaped piece of skin thus marked out was dissected up, and then pushed upwards as far as possible, and attached to the margins of the wound by sutures, whilst the gap left below the flap thus raised was closed by a hare-lip pin. The lid was by this means brought back to its proper place, but to keep it *in situ* and to shorten the elongated palpebral fissure, incisions were commenced in the lids at their outer extremities, and carried on beyond the commissure, where they were united. The triangular portion produced by these incisions was removed, and the edges of the wound closed by sutures. The case did well, leaving little or nothing to be desired.

The third case, that of E. J——, five years of age, came under my care in January, 1879, and is similar in character to the last. After measles, at the age of two years and a half, the bones of the face at various points became diseased, and now several depressed cicatrices were noticeable, the consequences of old sinuses. As a result also of one of these scars over the malar bone, the left lower eyelid at its outer part had become considerably everted, causing an ugly appearance. On Jan. 27th the case was treated in a manner almost identical with the one last referred to, and with an equally satisfactory result.

In conclusion I would refer shortly to another case in a man aged sixty-five (J. H——). From relaxation of tissues, as a result of senility, both lower eyelids had become pouted, permitting the tears to collect, and causing a chronically inflamed condition of conjunctivæ. The case was treated, the right eye on July 28th, and the left on August 4th, 1879, by removing a wedge-shaped piece of the lower lid at the centre, and uniting the edges by sutures. This produced shortening and relieved the eversion of the lid.

A MEDICO-TOPOGRAPHICAL REMINISCENCE OF THE WEST INDIES;

BEING CHIEFLY AN ACCOUNT OF THE HILL STATION OF NEWCASTLE, JAMAICA, WITH SPECIAL REFERENCE TO ITS CLIMATE AND ITS FLORA; IN CONNEXION WITH THE EXCEPTIONAL IMMUNITY FROM MORTALITY ENJOYED BY THE 29TH REGIMENT DURING THE YEARS IT WAS STATIONED IN THE COMMAND.

BY SURGEON-MAJOR BOILEAU, B.A., M.D.,

DIPLOMATE IN STATE MEDICINE, UNIV. DUBLIN, ETC.; ASSISTANT-PROFESSOR OF PATHOLOGY, NETLEY; AND FORMERLY MEDICAL OFFICER OF THE 29TH FOOT.

(Concluded from p. 562.)

IT is thought by many, and maintained by not a few, that the climate of Newcastle, Jamaica, is not tropical. This, however, is a mistake—a conclusion resulting, it appears to me, from a contemplation of but one factor only—elevation. A closer investigation dispels such a notion, and proves that the elevation of the station above the sea by no means insures that security against disease which it is credited with by those who look upon its climate as sub-tropical, or even warm-temperate, in comparison with that of the plains. It is quite true that persons coming up from the plains sometimes feel even cold as they approach Newcastle; yet its climate is tropical, as I shall now endeavour to prove.

I cannot more appropriately commence this part of my subject than by referring to the "Romance of Natural History," by Gosse, in which, alluding to the mountains of Jamaica, he quotes the words of Darwin—"the land is a great, wild, untidy luxuriant hothouse."[1] The biologist recognises the tropical character of the climate, for he sees that it is favourable to the production and propagation of numbers of tropical forms of life, and it is from one of his aspects of the case that I now propose to consider it. It is especially from a botanical point of view that I will dicuss the question. The botanist, then, perceives that the inhabitants of the cantonment are exposed to the influences which favour the growth of the banana and plantain forms of vegetation and of the suffrutescent *Malvaceæ*, such as *Sidas*, *Abutilons*, and *Hibisceæ*. Within the limit of his

[1] Vide p. 177, loc. cit.

Digitized by Google

afternoon walk he meets with the great Cotton-tree (*Eriodendron*), towering high as a landmark above all other growths; and the liana forms of the tropical forest twining in company with the curious *Marcravia umbellata*, the various *Ipomeas*, the *Melastomas*, and the *Piperaceæ*. He finds, amongst the succulent *Crassulaceæ* bounding his walks, the "life-plant," or "wonder of the world" (*Bryophyllum calycinum*), throwing up its panicle to the height of four or five feet. He finds arborescent ferns, growing to the height of thirty feet, in great abundance and in high development; whilst, on the other hand, he finds not a solitary example of the common or characteristic dicotyledonous trees of temperate regions. In place of the pine, plane, elm, oak, walnut, hazel, birch, beech, chestnut, or alder, he meets with cecropias, fig-trees, anonas, avocados, coffee; arborescent atropas and solanums, mangos, and other *Anacardiaceæ;* hog-plums (*Spondias lutea*), artanthes, and East Indian jambosas. In place of the familiar ivy, he finds arborescent forms of the same family—e.g., *Hedera capitata* and *Sciadophyllum Brownei*. In place of the common nettle, he finds a shrub (*Boekmeria caudata*); wild lantanas and durantas greet the citriodoras and flowering verbenas, imported from temperate climes. The only representatives of the heath form he can find are three trees, an *Andromeda*, a *Clethra*, and the polypetalous *Cyrilla antillana*. Of the poppy tribe he finds but a single example—the "John Crow bush" (*Bocconia frutescens*). He seeks almost in vain for the plants of cold climates, but finds the *Ranunculus repens* wandering from a garden, or, perhaps to his surprise, the *Leonurus sibiricus*, or the *Leontodon* of Britain. The familiar daisy he cannot find, whilst its tropical brothers and sisters he sees in countless numbers—e.g., *Vernonia arborescens*, *Ageratum*, *Eupatorium odoratum* and *glandulosum*, *Baccharis scoparia*, *Bidens leucanthus*, *Verbesina galinsoga*, *Emilia*, *Calea*, and shrubby *Senecios*, &c.; in fact, within half an hour's walk of the station he will find amongst many others the following plants—*Coccocypsilum repens*, *Dodonæa angustifolia*, *Phytolacca decandra*, *Crotolaria striata*, numerous forms of *Cassias*, *Mimosæ* and *Acacias*, and amongst them *Acacia vespertina*, the large white heads of which become so conspicuous at sunset, and the high climbing *Cassia viminea*, with its very black pods. He will find *Clusias*, *Rytidophyllums*, *Centrosolemias*, *Stachytarphas*, *Scutellarias*, *Rhipsalis cassytha*, *Tournefortia hirsutissima*, *Leianthus longifolius*, and among the orchids, *Bletia*, *Epidendrum*, and *Isochilus*, &c. To the above I might add numerous other plants, the locality and identity of which I determined in my walks about Newcastle; but I have given enough to prove from a botanical point of view that there can be little question about the climate being tropical. I would, however, appeal to the ornithologist with his humming birds, mocking birds, buzzards, Jamaica parrots (*Crotophagia ani*), and todies (*Todus viridus*), &c.; the entomologist, who would delight us with an account of the *Lampyridæ*, which in myriads gleam at night; of the magnificent *Urania sloanus* that flies in scores by day; of the "walking leaves" and "spectre insects" which baffle attempts to find them, and of the "trap-door" spiders whose nests excite such admiration. Lastly, I would summon the meteorologist himself as a witness in my case, who should admit that a temperature below 50° F. is scarcely known at Newcastle at any time of the year; that tropical sunsets, rains, and storms prevail, and that the average temperature is only 10° F. below that of the plains.

The water-supply at the station was excellent; there was a sufficiency of the purest water fresh from the clouds and from the mountain springs and streams, from sources far above the possibility of ochlitic or zymotic contamination. It was conducted by metal pipes, and as a rule was abundant in quantity, a rule to which there need not be any exception if the pipes and tanks were always kept in proper order. The latrines were on the dry-earth system, and it worked admirably, admitting at the same time of some improvements. The system had not been extended to the officers' quarters, and the latrines attached to these were still of the old style, constructed on principles ancient, primitive, and condemned—very great nuisances, and sooner or later certain to be, as they were before, causes of disease and death. The drainage proper, both natural and artificial, was all that could be desired. The lavatories and baths were in fair condition, but a large plunge and swimming bath was very much needed. It would have been a most valuable addition to the station, and the majority of the men would gladly have availed themselves of it. The rations were good, but as the men could very rarely obtain either fish or mutton, the never-ending beef became a very monotonous diet. Vegetables and fruit could be had in great variety and abundance, and the free use of them—instinctively indulged in—no doubt contributed much to the preservation of health.

The duties, drills, and parades were of a light and ordinary character. Knapsacks were not worn, and marching out parades were unknown. The means and opportunities of recreation were very limited; there was, it need scarcely be said, no place of public amusement within reach. All ordinary out-door games were excluded by the configuration of the place, and even walking was a matter of labour, if of inclination, in consequence of the surrounding hills. The artificial lighting of the barrack-rooms was decidedly bad, and thus the men had no inducement to remain in them after the short twilight following sunset. They were tempted by the allurements of the canteen, and intemperance, either in the form of drunkenness or in the less tangible form of physical and mental degeneration, was becoming latterly too common. I would here remark that three years is quite long enough for any regiment to be stationed at Newcastle. Life there becomes monotonous, and the consequences cannot be good.

In conclusion I will briefly mention a few of the circumstances which contributed to the extraordinary good fortune of the 29th Regiment in its not having lost a single life from endemic or epidemic disease during the three years and three months that it, or a portion of it, was stationed at Newcastle, Jamaica.

First, in point of time, and perhaps of importance, the regiment arrived in the West Indies from a very healthy command—Canada—where it had been for two years, and I would suggest for consideration the fact that the 84th Regiment, which suffered so severely at Newcastle, went to the West Indies from Malta. Two years in Canada must impart to the human economy a resisting power against morbific forces very different from that to be gained by a residence of the same length of time in Malta.

Secondly. The regiment passed inside Port Royal and the dreaded "palisades" at probably the very best season of the year. It disembarked at Kingston, *en route* for Newcastle, in the last week of December.

Thirdly. There was absolutely no sickness in the regiment when it landed.

Fourthly. Whilst the regiment was at the station, the nature of the duties imposed was such as gave the men sufficient employment to neutralise or prevent as much as possible the ill effects of *ennui*, and their strength was not taxed.

Fifthly. The men had an unusually large number of "nights in bed." Their turn for night duty came round very seldom. Constantly recurring night duty is most detrimental to health.

Sixthly. The hospital and everything connected with the sick was kept most scrupulously clean. I may say punctiliously so; to such an extent, indeed, that certain officials in the command thought proper to draw attention to our extravagance. We pointed to the results, and made no change.

Seventhly. The clinical thermometer was in constant requisition. By its use the admission of a man for inflammatory or febrile diseases—unless he really had such—was guarded against. On the other hand, it prevented the occurrence of any man reporting himself sick being sent to his duty when he should be admitted to hospital. Conclusions drawn from subjective phenomena were by its aid considerably modified, and the stage of a patient's convalescence to a great extent measured. There is, however, no need to dwell here on the advantages of clinical thermometry. My remarks on the subject are of course merely a text of the enlargement they admit of.

Lastly. The health of the regiment was greatly contributed to by the unceasing supervision exercised by all the officials concerned over every matter connected with the well-being of the men.

I have only to add to the above the reasons why every regiment nowadays should look forward with little or no apprehension to spending a few years at Newcastle, Jamaica, although it is a tropical station less than 4000 feet above the sea-level. The station is isolated, and at a distance from the haunts of men; thus, to a great extent, the introduction of contagious or infectious diseases is prevented. There are no low public-houses in the vicinity: a walk to the nearest would involve an amount of physical exertion which would

Digitized by Google

be considered by most men much too dear a price to purchase their pleasure at. There is a plentiful supply of water, drawn from the purest sources; and there is an abundant supply of a great variety of wholesome fruits and vegetables. The system of conservancy is that known as the "dry-earth," and the necessary work for its proper accomplishment is all done by a corps of natives known as the black pioneers. The white soldier has no work of this nature to do. The advantages of the dry-earth system, when it can be carried out properly, are admitted. In fine, the favourable influences of the locality are such that, in the presence of due vigilance and attention to the laws of hygiene, and the absence of epidemics, it ought always to prove as healthy as it did to the 29th Regiment.

HYDRONEPHROSIS; NEPHROTOMY; RECOVERY.

BY THOMAS SAVAGE, M.D., M.R.C.P. LOND.,
SENIOR SURGEON TO THE HOSPITAL FOR WOMEN, BIRMINGHAM.

MARY N——, aged forty-six, married twenty-one years, with five children, came as an out-patient Oct. 28th, 1879. She had noticed a lump in her abdomen for a year and a half; is quite regular, the last period being a fortnight ago. Has suffered from prolapsus uteri, for which she has worn various pessaries. She is thin, and looks careworn.

On examination there was a tumour about the size of a fœtal head, occupying the right lumbar and umbilical regions. It was elastic, very movable and painless, clearly a cyst, and appearing to spring from the right kidney. The urine was examined several times, and found to be normal. There was no history of pus or blood in the urine, nor of injury in any way, and there was no appearance of malignancy, but there was an indistinct history of renal colic, to which the patient referred as having occurred about three or four years ago, and which was marked by intense pain on the right loin, frequent micturition, and the necessity for constant application of hot fomentations. On repeated examinations, seeing that it sprang from above and had clearly no reference to the pelvis, that pressure on the right kidney pressed it forwards, and that there was resonance on percussion over one portion (the lower) of it, the tumour was diagnosed as a hydronephrosis, with a fairly long mesonephron. Very curiously, it was said to become smaller at the menstrual periods. As time went on the patient was sure the abdomen was enlarging, and this, together with the fact that she was getting thinner, and was now (January, 1880) quite unable to do her household work, induced a recommendation to come into hospital and submit to an attempt at removal, or, at all events, to allow us to make an exploratory incision.

On Jan. 16th the operation was performed, which consisted of a median incision, extending from about two inches above to two inches below the umbilicus. The tumour now exposed was seen to be cystic, and was covered by the upper layer of the meso-colon. It was tapped, giving exit to a clear, watery fluid; unfortunately this got mixed with blood, and was thrown away, and so neither the quantity nor the quality could be ascertained. When the hand was passed down to the base it was found that the attachment was very broad—i.e., thicker than one's wrist,—and it appeared impossible to tie the artery and the vein, as also to tie the mass in bulk, at so great a distance, deep in the abdomen, and close to the spine. The wall of the cyst on the outer and front part was made up of true renal structure—i.e., the dilated pelvis of the kidney, in which were seen the enlarged calyces and papillæ. The other part of the cyst-wall was evidently made up of two portions: an outer, being a continuation of the capsule of the kidney; and an inner, apparently derived from the lining of the enlarged pelvis. The hand was passed into the cyst in search of a calculus in the ureter, but none was found, and it was then sponged out with carbolic solution. A wire clamp was applied about the middle of the collapsed cyst, and about one-half of the distal portion—i.e., about one-fourth of the whole mass of the cyst—was cut away, leaving one-fourth still attached to the distal side of the clamp. This large mass was left for the sake of security against slipping. Perchloride of iron was applied to it, and carbolised lint applied as dressing. About the fourth day afterwards there was noticed a slight welling up of clear fluid in the centre of the stump, which appeared likely to eventuate in the presence of a persistent urinary fistula. The clamp was cut away on the twenty-third day, and the sloughing stump gradually cleaned, so that the patient left the hospital on March 1st.

When seen again on March 15th, at my house, the wound had cicatrised with the exception of an area about the size of a threepenny-piece, at the bottom of which was a sinus, into which a probe passed for two inches directly backwards and without pain or bleeding. The patient stated that there was a daily discharge of clear fluid of from a tea- to a table-spoonful in quantity. She appeared to be quite well in herself, and there was no tumour to be felt. She expressed herself as being better, and much more comfortable than before the operation.

Remarks.—The surgery of the kidney has of late attracted a considerable amount of attention, more especially with regard to the subject of nephrotomy; and several cases have recently occurred which tend in the direction of making it a justifiable and recognised operation. This has no doubt been brought about by the greater safety of abdominal section now compared with what formerly obtained. It may be deemed suitable in some few cases, in the early stages, of encephaloid and sarcoma; in hydronephrosis, as in the case related; and in pyonephrosis, where the patient is in a state of hectic, or, rather, before that stage, if possible, has come on; and for the removal of calculus in the ureter or in the pelvis.

There appear to be certain difficulties connected with the operation which have occurred to my mind since I operated on the above case. First, there is the thickness of the so-called pedicle or base, which at so great a depth may prove a considerable hindrance to successful ligature and subsequent cutting away. Of course the clamp is out of the question for the entire removal of the kidney, as the mesonephron would seldom, I imagine, be long enough to be brought up to the abdominal wall: and kidney tumours are often very deceptive in this respect, appearing to be freely movable in all directions nearly all over the abdomen, but found to be in reality rather firmly bound down. The clamp could be applied only to the tumour itself, as in my case, and then it is a question how far the part of the cyst left attached may not continue to be a secreting surface, and so the patient, perhaps, be no better for the operation, or leave a fistulous tract, which, though relieving a hydronephrosis, is, to say the least, not a pleasant accompaniment to one's ordinary life troubles. Secondly, there is the difficulty, I imagine, in many cases of having to pass a ligature round so short a vessel as the renal artery and vein are; and, thirdly, there is the question whether, when a ligature has been passed, the shortness of the vessel, and therefore the close proximity of the ligature to the great vascular trunks, will not prevent thrombosis occurring in the proximal side of the ligature, and hence permanent occlusion. I am not prepared to answer these points, but they are such as have occurred to me in thinking on the subject.

The cases reported by Simon, Czerny, Martin, Zweifel, and more recently by Knowsley Thornton and A. E. Barker, will do much to bring nephrotomy and nephrectomy before the profession; and the foregoing case is recorded with the same view.

MEMORANDA ON SKIN DISEASES.

BY H. STANLEY GALE, M.B. LOND.,
PHYSICIAN TO THE MANCHESTER SKIN HOSPITAL.

HERPES GESTATIONIS.

TWO cases of this rare disease having been treated—successfully, I believe—by me during the last four years, and a third case being still under notice, it may be worth while to describe the treatment adopted.

When I saw the first of these cases I was struck with its similitude to "recurring pemphigus" (not Hutchinson's "cheiro-pompholix") both as to appearance and course. Of this latter disease I have seen several examples during the last few years, two or three of which cases had lasted three or four years, while one had lasted nine. These were treated upon general principles, the application of which in

Digitized by Google

most of these cases consisted in the internal administration of quinine in doses of three grains, when the patient could stand it, and iron when required. Cod-liver oil was added in scrofulous cases. The local treatment consisted in pricking the blebs, turning back the skin, and rubbing the spot freely with lunar caustic. The pain was severe, but all the cases were cured. (I give no details, as I am not writing of pemphigus). Struck with the resemblance, I adopted similar treatment in my cases of herpes.

Mrs. H——, housewife, aged thirty-nine, had suffered from herpes on six occasions. The eruption had usually appeared about four days prior to her confinement, and gradually increased in severity up to three weeks after that event. The blebs appeared the day after confinement, the rash before that resembling erythema papulatum. When I saw the patient first, a few days before her confinement, she was in such an irritable state that she could with difficulty hold a cup in her hand. All ordinary local sedative applications were of no avail. It was not, therefore, till the blebs appeared, and lunar caustic freely applied, that relief was given. A slight amount of irritability which remained was removed by the local application of vaseline and a hypodermic injection of morphia. After two or three applications of caustic the patient said she felt "as if in heaven." I may add that the morphia by itself does no permanent good. This woman has been confined once since without the slightest symptom of the disease, although she had suffered from it at every preceding pregnancy.

Mrs. B——, a baker's wife, aged thirty-four, suffered much from gastralgia, probably due to eating new bread. (She said she married a baker so that she could indulge this taste.) Her symptoms were, in the main, similar to those of the last case, but she did not suffer at every confinement. "On and off" she had the disease for eleven years—i.e., eight confinements. The patient, an intelligent woman, states that it was milder than usual when it reappeared after its absence during one pregnancy, and still milder after its absence during two. Previous to her last confinement but one this patient suffered for eight months from chronic eczema, and took during that time small doses of arsenic. The eruption broke out as usual, apparently unaffected by the drug. Lunar caustic was applied as in the last case, and immediately afforded relief. This patient has been confined since without any reappearance of the disease.

There can hardly be a doubt that these cases (herpes gestationis, pemphigus, and hydroa) depend upon some affection of the nervous system. They are all benefited, more or less, by nervine tonics, and accompanied by pain or nervous irritation amounting at times to almost complete prostation. I may add that my cases differed from those recorded by Milton in the following particulars, viz.:—1. No stain was left after involution. 2. In one case the eruption was chiefly on chest, abdomen, and back, and hardly at all on the limbs. 3. No solid papules, merely the condition seen in mild erythema papulatum. 4. Neither blebs nor vesicles till after delivery. 5. Neither grouping of vesicles nor crusting (when left to themselves). Lastly, there was no inflamed base to the vesicles. This confirms Dr. R. Liveing's opinion that the disease should be called "hydroa."

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tam aliorum, tam proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. BARTHOLOMEW'S HOSPITAL.

[OUT-PATIENT DEPARTMENT FOR DISEASES OF THE SKIN.]

FIVE CASES OF LOCALISED SCLERODERMA; REMARKS.

(Under the care of Mr. MORRANT BAKER.)

FOR more than two years Dr. J. Herbert Stowers has registered for Mr. Baker the cases of special interest in the department for diseases of the skin, and among them are the following cases of localised scleroderma or morphœa, or Addison's keloid, as it was formerly called:—

CASE 1.—Anne H——, aged twenty-one, a well-developed girl, with dark-brown hair, and somewhat florid complexion, attended on May 17th, 1878. The disease was first noticed six months before. Upon the right cheek, situated over the malar bone, there existed a circumscribed induration, circular, and measuring 1½ in. by 1 in. The skin was closely adherent to it, although the indurated mass itself moved freely over the subjacent bone. There was scarcely any visible superficial change in the skin. Some itching was complained of. Upon the left side of the face, situated also over the zygomatic process of the malar bone, an indurated and slightly prominent mass of integument was felt, measuring about 2 in. by ½ in. The colour of the skin was red, with a tinge of purple, but not sufficiently distinct to enable one to trace the outline with the unaided eye, the colouring not being coextensive with the margin. The skin was thick and "brawny," and could be taken up between the finger and thumb by its edges, feeling like a plate of semi-cartilaginous tissue. Sensation upon both sides of the face was unimpaired. The patient's general health was good, and the catamenia regular. The rest of the skin of the body was unaffected. No other member of the family had suffered from any cutaneous disease.

The patient was ordered to take three grains of iodide of potassium, with aromatic spirits of ammonia, thrice daily, and to apply a lotion of the subacetate of lead frequently. She was advised to shield the affected parts from exposure and all forms of local irritation as much as possible. After a week the prominence over the left malar bone appeared slightly less marked, but as on June 14th no further visible change having occurred, a draught containing five minims of arsenical solution with a little carbonate of soda and infusion of calumba was prescribed to be taken three times daily, and zinc ointment replaced the lotion.

On July 26th there was slight apparent decrease in size on both sides of face. Redness was less apparent.

On Sept. 13th on both sides the diseased integument appeared to be sinking in at the centre, and possibly from this cause was slightly more raised and tuberculated at the margin. The diameters remained the same. The itching originally complained of was less.

On June 24th, 1879, there was hardly any change in the condition of affected parts. The patient has not since attended.

CASE 2.—Harriet S——, aged eleven, attended on July 8th, 1878. She had never been a strong child, and had complained much of headache, giddiness, &c. Her skin had been quite clear until the end of March. The rash first appeared in irregular patches, which were red, scaly, and dry. It was stated that after the lapse of a few weeks the redness and scaliness disappeared, and a white, shining, somewhat indurated cicatrix or mass was left, but the scaly spots upon the left side of the face at the visit looked merely like spots of pityriasis simplex. The rash was confined to the face; the child had never complained of pain or itching. There were two other children living in the same house, but they were quite well, as was also the mother. The patches of morphœa were confined to the right side of the face. The largest, which was 1¾ in. by ½ in., extended from near the angle of the jaw, and passing forwards parallel to the margin of the lower jaw, terminated one inch from the angle of the mouth. Its edges were clearly defined. At the lower margin there was distinct redness from capillary injection. Below the right angle of the mouth there was a white patch, nearly circular, about the size of a fourpenny piece, and having a somewhat bluish outline. On the prolabium of the upper lip there was another white patch, about the size of a split pea. This was confined to the right side. There were three very irregularly-defined patches below the margin of the jaw in the submaxillary triangle. All the places were indurated.

On Nov. 28th, 1879, the following notes were made:—The patient has enjoyed continuous good health since last seen (more than a year ago). The right cheek presents no evidence of fresh disease, or extension of old patches. A slight dry eczema is present over the chin and upper lip. The two original patches of localised scleroderma present no changes, excepting that of almost complete absence of induration. The parts, however, when taken up between the finger and thumb, feel a little thicker than natural. Sensa-

Digitized by Google

tion is still below normal. Some slight degree of shiny whiteness, about the size of a shilling, is observed in the centre of the left cheek, also in the form of a straight line running down the forehead just to the left of the centre, about a quarter of an inch in width; also upon the right side of the nose, commencing immediately under the right eyebrow, and ceasing about half an inch from the apex. This is best seen when looked at obliquely. No structural change manifest; integument quite natural to the touch; sensation unimpaired.

CASE 3.—Catherine C——, aged twenty-nine, married, four children, first attended on April 25th, 1879. The disease began nine months before. There was no pain, but some itching was complained of. There were several patches of morphœa scattered over the lower part of the abdomen and back, extending to the upper and outer parts of both thighs. There was also a patch on the inner side of the left thigh. The affected integument presented all the usual characters, but with less thickening than usual. The colour was a faint yellowish-brown. There was also a patch commencing over left clavicle. Ordered zinc ointment to be applied locally, and syrup of the phosphate of iron and cod-liver oil internally.

No later opportunity occurred of taking a note of this case, as the patient did not attend, and a letter written to her address was returned on account of her having left the neighbourhood.

CASE 4.—Annie D——, aged twenty-four, married, one child, attended on Nov. 7th, 1879. The disease was first recognised five months before. Some itching was complained of. There was only one patch, and it had these typical characters. The sensibility slightly impaired. It was situated beneath the right mamma. Diameters 2 in. by 1½ in. The patch was raised and well-defined, whitish-yellow in colour, with reddish margin of capillary congestion. The general health was good. Zinc ointment was ordered for the relief of the itching.

On Nov. 28th there was no noticeable change. General health continued unimpaired.

On Jan. 30th, 1880, the patient expressed herself as much relieved of the irritation from which she previously suffered, but there was no apparent change in the condition of the patch of morphœa.

CASE 5.—Charles L——, aged thirty-six, a pattern-maker, married, four children. This patient was first seen by Mr. Baker three years ago, the disease having been then in existence for seven years. The patches of scleroderma, of which there were several on each side of the abdomen, and also upon the upper part of Scarpa's triangle, were nearly symmetrically placed. They were firm, smooth, and yellowish, with unimpaired sensibility; mostly of oval outline, the long axis running in all alike, parallel with Poupart's ligament. Most of the patches measured from one and a half to two inches in their long diameter. Itching was at first a prominent symptom.

The patient ceased to attend, and was not seen again until Nov. 28th, 1879, when the following note was taken:—The special change noticeable about the patches is that the former whiteness, with reddened margin, has given place to a dark-brown pigmentation, corresponding in extent and site with the patches formerly noticed. The integument is quite smooth and soft, the induration having completely disappeared. Upon the right side of the abdomen four or five patches of dark pigmentation are also to be seen. A larger mass of darkened skin, with here and there a white spot, corresponds with the inguinal fold, similar in extent and position to that on the left side. No alteration in sensibility at this time; general health good. Mr. Godart, the librarian, has made two water-colour drawings which show well the alteration that has occurred.

Remarks by Mr. BAKER.—Cases of localised scleroderma or morphœa are so rare that it seems well to place on record an accurate note of those which are observed; and it is with this object, and not because the foregoing cases show any very exceptional characters, that they are here recorded. The disease, moreover, is spread over so long a period in each individual case that the patients are apt to present themselves at various intervals before different observers, and it is hoped that these brief notes may be of service to others under whose care the patients may happen to be in the future, by enabling them to estimate the changes which the disease has undergone, and to contribute, thus, valuable facts with regard to the natural history of this puzzling affection.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

WHOOPING-COUGH IN A MAN OF SIXTY-SIX TREATED WITH DROSERA ROTUNDIFOLIA.

(Under the care of Dr. MUSKELL.)

William H——, aged sixty-six, the beadle at one of the City churches, attended the hospital in January, 1879, suffering from whooping-cough. He stated that he had had it for about three months. The attacks of coughing ended up with a distinct whoop and a violent struggle for breath. He had usually six or seven bad attacks in the day. They were not accompanied by vomiting, but terminated in the expectoration of thick sticky phlegm. The cough was most violent, and exhausted him very much, and he was glad to lie down after each paroxysm. There had been no hæmoptysis, no shortness of breath, and no night-sweating. He had lost flesh a little, but this he attributed to his loss of appetite. He was hoarse, and could not lead the singing as usual. His chest was carefully examined, but nothing wrong was detected. There was no doubt about the nature of the complaint, and one Sunday morning he whooped in church, to the consternation of the congregation. He had been exposed to whooping-cough, more or less, all his life, and thought he had caught it from some of the school children. This was his second attack, for he had had it as a child. He mentioned incidentally that his wife had it when she was sixty.

He was ordered fifteen grains of bromide of potassium in an ounce of water three times a day, and this he took for a fortnight with only slight benefit. He was then ordered a one-in-ten tincture of drosera rotundifolia (THE LANCET, August 3rd, 1878), in five-drop doses, every four hours, in a little water. He took this for a week, and then returned, saying that it had made him much worse. It increased the spasm and cough, and made him whoop more; he whooped as many as a dozen times in a single paroxysm of cough. It increased the expectoration too, and he begged that he might be allowed to discontinue the medicine. He was then ordered half-drop doses of the same tincture in half an ounce of water every three hours. At the expiration of a week he reported that there had been a very great improvement; the cough was less, and he rarely had more than one attack in the twenty-four hours. He slept better, and his appetite had improved. He took the medicine for a fortnight longer, when the cough had completely left him. He was quite well, and was able to sing bass and lead the choir once more.

The points of interest in the case are—the age of the patient and the fact of the drosera having succeeded in small doses after having failed in large.

FOLKESTONE INFIRMARY.

DOUBLE SIMULTANEOUS AMPUTATION OF LEGS JUST BELOW THE KNEE-JOINT; FRACTURE OF LEFT HUMERUS; LARGE SCALP WOUND; RECOVERY.

(Under the care of Mr. TYSON.)

A CASE very similar to the following was recorded in THE LANCET for Dec. 27th, 1879, by Mr. Hewetson of York.

J. H——, aged nineteen, a fireman, in the employment of the South-Eastern Railway Company, whilst changing the lamp in the front part of the engine, missed his footing and fell, and the wheels of the engine passed over his legs. The train was at the time of the accident slowly approaching Shorncliff station. The accident happened at 10 P.M. on Oct. 10th, 1879. About one hour later he was conveyed in a fly to the infirmary, a distance of a mile and a half.

On admission the general condition was unexpectedly good, the pulse being 80 and strong in character. The man was perfectly sensible, and appeared to have suffered little from the shock of the injury. There was no bleeding going on, nor had he, as far as could be ascertained, lost more than a trifling amount of blood. Both legs were crushed from the centre of the tibia downwards, and one was only just hanging to the body by a thin piece of tissue.

It was decided to amputate as near the seat of injury as possible, on both sides. At midnight chloroform was ad-

Digitized by Google

ministered, and the left leg was amputated in the upper third by Mr. Bateman (senior surgeon) by circular flaps, and the right leg by Mr. Tyson in a corresponding position, by antero-posterior flaps, the posterior one being transfixed, and including the muscles. A strong elastic cord was applied just above the knee-joint during the operations; only about two ounces of blood were lost; the vessels were ligatured with silken sutures. The left humerus, which was fractured in the middle, was set in the usual way. A scalp wound extended from the root of the nose, across the forehead in a semicircular course, as far as the external angular process. The wound was washed, and the edges brought together by interrupted wire sutures. The scalp wound rapidly healed by primary union, and the fracture was firmly united at the end of a month.

The stumps of both legs from the time of the operation progressed favourably; they were dressed (after the first dressing, which was of dry lint) with carbolic acid lotion and oil, then wrapped in cotton-wool. The spray was not used. Daily notes of the case were not taken, but the constitutional symptoms were comparatively mild; for beyond a slight increase of temperature and a pulse of 120° for two or three days after the operation, he appeared to ail little. The pulse was always under 100 (generally between 80 and 90), except during an attack of inflammation in the left stump about a month later, which gave rise for a few days to some feverish symptoms. He left the infirmary March 17th, 1879, walking on pin stumps, and in good health.

It may be added that the patient was a healthy young man, and had always lived an extremely steady life. The main cause of the success of the case may perhaps be attributed to the trifling loss of hæmorrhage before the operation.

NEWARK HOSPITAL.

TORTICOLLIS; INJURY TO RIGHT STERNO-MASTOIDEUS; ASCARIS VERMICULARIS.

FOR the following notes we are indebted to Mr. J. D. T. Reckitt, L.R.C.P., house-surgeon.

Fanny M——, aged three years, attended as an out-patient on February 18th. Her grandmother stated that a fortnight ago the child, whilst apparently in perfect health, was playing under an upright ladder, which fell across her chest and right clavicle, bruising the latter considerably. The next day a swelling was noticed at the sternal end of clavicle, and the head was pulled down towards the right shoulder. The child complained of pain over the swelling, which, together with the altered position of the head, continued till admission, the latter getting worse. When first seen, the child presented a healthy appearance, the head was considerably flexed towards the right shoulder, and the chin pointed over the left. There was a small swelling over the sternal end of clavicle about the size of a pigeon's egg, but no displacement of that bone, the swelling being evidently due to effusion into the sheath of the muscle (sterno-mastoid) at this point. On attempting to straighten the head much pain was caused. There was no history of worms.

Pressure was applied over the swelling at sternal end of clavicle by means of a pad of lint. A pad was placed in the axilla to keep the bone at rest, and the arm securely bandaged to the side, a suspicion arising that there might possibly be some reflex irritation from worms. Four ounces of concentrated infusion of quassia were injected, and directions were given that the motions should be inspected, and the child brought in three days.

The child was freely purged by injection, and many thread-worms were expelled. On the 21st, the neck was much straighter. Repeated injection. On Feb. 25th, more worms had been passed; the neck was quite straight; and swelling over sterno-mastoid was gone.

Remarks.—The interesting point appears to be that though the ascaris vermicularis was perhaps the main cause in producing the wryneck, yet that condition did not appear until another exciting cause in the injury by the ladder was brought to bear upon the case. Then, again, the disappearance of the effused fluid in the sheath of the sterno-mastoid simultaneously with the worms by aid of injections of quassia, makes it almost difficult to decide whether to ascribe the cause to the idiopathic or traumatic nature.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Syphilitic Stenosis of Pharynx.—Partial Metabolism by the Liver of Leucin and Tyrosin into Urea.

THE ordinary meeting of this Society was held on the 13th inst., J. E. Erichsen, Esq., F.R.S., President, in the chair. A remarkable case of extreme pharyngeal stenosis, due to syphilis, and relieved by operative measures, was communicated by Dr. Gilbart Smith and Mr. Walsham.

The following is an abstract of the paper, entitled "A Case of Extreme Pharyngeal Stenosis the result of Syphilis; with Remarks." By T. GILBART SMITH, M.D., and W. J. Walsham, F.R.C.S. The subject of this case was a woman, forty-seven years old, who was admitted on Oct. 29th, 1878, into the Royal Hospital for Diseases of the Chest, under the care of Dr. Gilbart Smith, suffering from prostration and dysphagia, accompanied by severe and recurrent attacks of dyspnœa. She gave a clear history of syphilis, which she had evidently contracted soon after her marriage twenty-six years before. She suffered for the first time ten years ago, from ulceration of the throat. This was relieved by treatment, but recurred at intervals up to the time of her admission. Eight months ago her voice became affected, and the movements of the tongue impeded. For six months she had been unable to swallow food, and for two months had suffered from severe and alarming attacks of dyspnœa. The tongue could not be protruded beyond the teeth; the right posterior pillar of the fauces was drawn backwards, and was adherent to the posterior wall of the pharynx. The uvula and a considerable portion of the soft palate had disappeared, leaving a clean semicircular border to the portion that remained. On laryngoscopic examination the epiglottis and vocal cords could not be seen, but an aperture was visible one-eighth of an inch in diameter at the bottom of a funnel-shaped depression to the left of the middle line on a level with the epiglottis. This was separated by a thick cicatricial band from another and deeper depression to the right, which terminated in a cul-de-sac, containing pus. This small aperture, after considerable difficulty, was made out to be the only entrance to the larynx and œsophagus. Tracheotomy was performed by Mr. Walsham on November 1st. On November 24th attempts at dilatation were made, and on succeeding days repeated, but they failed to produce any material benefit. Stretchings by means of laminaria and sponge tents could not be borne. On Dec. 5th Mr. Walsham partially divided the cicatricial band bounding one side of the aperture with M. Ricord's urethrotome. On the 8th it was further divided with a pair of curved scissors. One blade being placed in the aperture, the other in the ulcerated depression, incision was made little by little from above downwards so that a full view was obtained of the cut surface of the tissues, and any vessel, if divided, could be seen and secured. Care was taken to enlarge the aperture as much as possible in such a direction as would allow the food in passing downwards to avoid the entrance into the larynx. The parts were then forcibly dilated by the finger and œsophagus bougie. On Dec. 12th another incision was made at a different spot, and the epiglottis, vocal cords, and arytenoid cartilages came into view. When the patient left the hospital, Dec. 18th, the aperture measured three-quarters of an inch in diameter, and admitted a full-sized œsophagus bougie. On Sept. 23rd, 1879, she was again seen by Dr. Gilbart Smith. The aperture had not contracted in the least. Stenosis of the pharynx appears to be very rare. The authors describe three distinct forms. The first, the most common, is situated between the naso- and mid-pharynx, and is caused by ulceration and contraction of the posterior pillars of the fauces, and the drawing backwards and subsequent adhesion of the soft palate to the pharyngeal wall. Cases of this kind are reported by Messrs. Bradley, Cheevers, Reid, Coulson, and Schech. The second form is more rare; it occurs between the mouth and the pharynx, and is produced by the ulceration and contraction of the anterior fauces and the drawing downwards and

Digitized by Google

subsequent adhesion of the soft palate to the dorsum of the tongue. A case is reported by Mr. West. The third variety involves the lower part of the pharynx, as in the case now before the Society; the stenosis being produced by bands of adhesions or soft or tough membranes, which stretch across the pharynx, and glue the parts together. Other similar cases are reported by Schech, Gerhardt, Trendelenburg, Schroetter, West, and Cheevers. The authors draw the following conclusions:—1. That tracheotomy is called for both as a temporary expedient to obviate sudden death from asphyxia, and as an essential factor for safe and satisfactory treatment. 2. That division, with a guarded knife, presents advantages over other methods of treatment. 3. That several small notches are preferable to a deep incision, and that, when possible, the parts should be divided from above downwards, so as to allow a full view of the surface of the tissues divided. 4. That the aperture should be enlarged in a direction so as to permit the passage of liquid food clear of the entrance to the larynx.—Dr. HABERSHON said that the case was of great interest from its rarity and from the relief afforded by the operation. Syphilitic contraction of the upper part of the pharynx was not uncommon, but stenosis in the situation in this case was rare. He asked whether the contraction was wholly attributable to antecedent ulceration, or whether there was any evidence of new growth—as occurs in advanced syphilis. He also asked whether internal treatment—e. g., mercury and iodide of potassium—was followed after the operation.—Dr. SÉMON congratulated the authors upon their success in dealing with so intractable a disease as syphilitic contraction. As a rule, simple dilatation alone was insufficient, the contraction recurring after the dilatation was left off. The preliminary tracheotomy was a wise measure, especially in the case of so narrow a stenosis as existed here. He commended the employment of gradual dilatation aided by small incisions, and said that the latter might also be made by the galvano-cautery loop, which diminished the risk of hæmorrhage. The observations of Gerhardt as to the greater liability to syphilitic ulceration of the upper over the lower respiratory passages were confirmed by a recent analysis of 10,000 cases (shortly to be published) of throat disease, 1100 syphilitic, 800 of these involving the pharynx and 300 the larynx.—Dr. FAGGE inquired whether the stenosis was wholly attributed to cicatrisation of ulcers; for he had remarked the occurrence in some cases of tracheal and bronchial stenosis without any evidence of ulceration. He had seen a case of syphilitic stenosis low down in the pharynx. The patient was under Mr. Durham's care, for stenosis of the larynx. A year later the pharyngeal stenosis became declared, and dysphagia was very extreme. Mr. Durham succeeded in relieving the patient by the passage of bougies. Mercurial fumigations were also practised in that case.—Mr. GANT asked whether the dilatation was continued after the cutting operation. He had failed in overcoming such obstructions by dilatation alone; but judging from the analogy afforded by rectal strictures, he would think that dilatation practised after incision would obviate the return of the stenosis.—Dr. R. THOMPSON thought it would have been well to have administered nutritive enemata during the treatment of the case. It would have given the affected parts rest, and supported the patient during the dysphagia.—The PRESIDENT said that many years ago he had observed by experiments on animals that the sensibility of the glottis was always much diminished after tracheotomy; so that food passing into the larynx no longer created spasm. He had noticed this also in cases of cut-throat and after tracheotomy in man. This appeared to have been so in the case related; and the point was one of importance as favouring the performance of a preliminary tracheotomy, which does not complicate subsequent operative measures, and relieves the patient from the risks attending on them.—Dr. GILBART SMITH, in reply, said that iodide of potassium was administered freely during the whole course of the case. There was active ulceration going on by the side of the cicatricial tissue; and there could be no doubt that the new tissue and thickening were due to previous ulceration. The relief afforded to the dysphagia by the operation obviated recourse to nutrient enemata, although perhaps they might have been resorted to with advantage. The effect of tracheotomy in arresting spasm of the glottis was an important fact. Allied to it was the occurrence in some cases of paralysis of the laryngeal muscles from the use of tracheotomy tubes; which has led to the suggestion that the tube should have an aperture made in it to allow of passage of air into the larynx from below, whilst the tube is worn.

A paper was then read "On the Partial Metabolism by the Liver of Leucin and Tyrosin into Urea," by EDWARD CHARLES ANDERSON, M.D., of which the following is an abstract:—"The presence of leucin and tyrosin in the urine of man, in the course of numerous diseases, shows that it is a function of the healthy liver to decompose them partly into urea, and to thereby prevent their undue accumulation within the system." It has been, and still is, universally taught and accepted that leucin and tyrosin are present, most especially in acute yellow atrophy of the liver—an exceedingly rare disease,—that, in addition, one or both have been discovered by Beale in chronic wasting of the liver, and in leucocythæmia; by Frerichs and Städeler in typhus, small-pox, and some of the other exanthemata; and Balfour infers, if he does not state positively, that they, or at least certain abnormal constituents, were present in the urine in a case of obstruction to the hepatic circulation, due to valvular disease. Murchison, however, attributed their presence in typhus, &c., as due to concurrent acute atrophy. Having met with, on Nov. 11th, 1877, a case of jaundice arising from obstruction, Dr. Anderson, more through curiosity than from anything else, examined the urine for leucin and tyrosin, and discovered them; moreover, finding that during convalescence first tyrosin disappeared and finally leucin, and that during each return of the symptoms, on future slight recurrences, leucin reappeared, he determined upon prosecuting strict and extended research for these constituents in as many pathological manifestations as came under his notice. As a result, out of thirty-three individuals (about ten of whom came under his care frequently, and therefore, counted as cases, their numbers would exceed sixty) in whose urine either leucin alone or tyrosin and leucin existed, there were of jaundice, two; mitral and aortic incompetency, one; cirrhosis, one; acute rheumatism with pneumonia, two; nephritis with dyspepsia, one; anæmia, one; phthisis with intestinal obstruction, one; phthisis, one; colic, one; pleuro-pneumonia, two; chronic bronchitis, one; hepatic derangement, five; emphysema, two; Bright's disease with presystolic and mitral systolic bruits, one; bronchitis with asthma, one; acute rheumatism, one; chronic and spasmodic asthma, three; puerperal eclampsia, one; delirium tremens, one; hemiplegia, one; pertussis, one; cancer of liver, one; puerperal septicæmia and embolism into base of right lung, one. That is to say, there were over eighteen or nineteen different diseases in which either leucin alone, or tyrosin and leucin were present; and differing in two senses; for, firstly, they differ among themselves, and, secondly, because they do not include either acute yellow atrophy, chronic yellow atrophy, typhus, small-pox, or the other exanthemata. Tyrosin is said to generally accompany leucin, but it was absent in nineteen out of the thirty-three individuals; moreover, it most usually occurs in only the severer manifestations of disease. Some physiologists assert, but by others it is disputed, that, in certain cases, urea is almost completely replaced in the urine by leucin and tyrosin. Beale found tyrosin in considerable quantity in urine which contained much uric acid. In the case of puerperal eclampsia, out of a total of five fluid ounces of urine passed in three days, albumen was copious; uric acid in enormous quantity; urea in only minute amount; much leucin and tyrosin. In the hemiplegia cases at the commencement, albumen was very appreciable; leucin abundant; urea deficient. Within a week of taking euonymin nightly albumen was reduced to a mere trace; leucin greatly lessened; more urea and water in urine. Under similar treatment a like increase of urea and diminution of leucin, or of tyrosin and leucin, occurred in Nos. 12, 23, 24, 25, 26, 29, 30, 31, of the individuals whose diseases are recorded. Dr. Anderson is, therefore, of opinion that the presence of leucin and tyrosin in the urine is due to a corresponding deficiency of urea; that this is not invalidated by the circumstance of the simultaneous existence of much leucin and tyrosin and increased quantity of urea, for during great destructive metabolism, such, for instance, as occurs in the course of many diseases, the liver is so overtaxed as to cast into the blood, not only urea in large amount, but the overplus of waste—viz., leucin and tyrosin; moreover, as convalescence advances, although the absolute quantity of urea daily eliminated may have become less, the most marked and progressive diminution takes

Digitized by Google

place in leucin and tyrosin; and, as the author has shown, occasionally in albumen and uric acid. As a strong presumption in favour of the theory that among the many functions of the liver the formation of urea from leucin, if not from tyrosin, may be ranked as one, it has been instanced that in cases of acute atrophy of the liver, where the hepatic gland cells lose their functional activity, the urea of the urine is replaced by leucin and tyrosin. If such be the case, the inference seems irresistible that the numerous diseases in which leucin and tyrosin (one or both) are shown to have been present; their diminution during convalescence; reappearance and increase during each return and exacerbation of the symptoms; their final disappearance and the order of it—viz., firstly tyrosin and then leucin; the circumstance that tyrosin appears only in and during the severer manifestations; their increase and diminution in inverse proportion to the amount of urea; and, lastly, the influence exerted by the preparations of salicin and euonymin (well known hepatic stimulants) in increasing the quantity of urea and in diminishing that of leucin and tyrosin, strengthen and support this theory in the fullest possible manner. Frerichs asserts that leucin and tyrosin are found only in the *hepatic* and *not in the portal vein*. This would seem irreconcilable, in the face of so much to the contrary, but for one possible explanation—viz., that afforded by the early stages of so-called nutmeg liver. Here, owing to "remora," there is congestion and partial stasis of the contents of the intra-lobular veins, and consequently pressure upon and interruption to the functional activity of the gland-cells immediately surrounding them.

CLINICAL SOCIETY OF LONDON.

Sympathetic Ophthalmitis after Excision of Eyeball.—"Bone-setting."

THE ordinary meeting of this Society was held on the 9th inst., Dr. E. H. Greenhow, F.R.S., President, in the chair. After Mr. Nettleship had read some interesting cases of sympathetic ophthalmitis following excision of the eyeball, a debate took place upon "bone-setting." It arose out of a communication by Mr. Howard Marsh, who, after giving details of certain cases which had come under his own notice, enumerated the various kinds of disease which were sometimes successfully treated by bone-setters. The debate occupied the greater part of the evening, and was shared in by Messrs. Hulke, J. Wood, T. Smith, C. Heath, Barwell, Brown, H. Morris, and Prescott Hewett.

Dr. STEPHEN MACKENZIE exhibited a case of Elephantiasis treated by Elastic Bandage, and Mr. CLUTTON one of Acquired Hypertrophy of one Lower Limb.

Mr. NETTLESHIP read notes of Three Cases of Sympathetic Ophthalmitis setting in three weeks after Excision of the other Eye. The first case was one in which excision was practised for the removal of a shrunken eye, with fluid cataract and corneal nebulæ following purulent ophthalmia. Twenty-two days after there was some dimness of vision in the left eye; this increased. Neuro-retinitis, followed by irido-cyclitis and chronic glaucoma, ensued. Iridectomy did not much reduce the tension of the eyeball, and permanent blindness ensued. The second was a case of rupture of the left eyeball from a blow with a screw-driver. The wound was of moderate extent, was united by single suture, and iced compresses applied. But inflammation followed, and excision was had recourse to nineteen days after the accident. Twenty-nine days after the excision acute iritis set in in the right eye, and then detachment of retina; the vision became impaired, but subsequently recovery took place. The third case was one of excision for injury to the eyeball twenty-four days before. Twenty-five days after the operation the remaining eye began to inflame, and vision was permanently impaired, but not wholly lost. Mr. Nettleship remarked that he had found notes of six published cases, in one of which the ophthalmitis set in the remaining eye five days after the excision, and in the others three days, two weeks, eight days, and forty-one days respectively. He did not think the ophthalmitis was due to the operation, but to the original disease. It was notable that out of eight cases there had been six recoveries. These cases strengthened the insistance upon early removal of eye spoiled for useful sight, and likely to set up sympathetic disease.—Mr. SPENCER WATSON questioned whether the eyes which became inflamed were not primarily diseased eyes. This seemed probable in the first case. He thought that the cases showed the importance of care in the after-treatment of excision of the eye, but he had never met with a case of ophthalmitis attributable to the operation.—Mr. NETTLESHIP did not think the other eye was diseased in his first case, where the cataract depended on perforation of the cornea.

Mr. MARSH read some cases of "Bone-setting."—No. 1. A countryman, aged fifty, dislocated his shoulder. The dislocation was at once reduced, and the arm bandaged to the side. Nine weeks afterwards he came to London for advice. It was found that the limb was so stiff that he could not move the elbow more than two or three inches in any direction; and any movement, whether on his part or during examination, produced great suffering; and he complained of constant severe aching from the shoulder to the elbow. It was noticed, however, that the joint was quite free both from heat and swelling. When he had taken gas the scapula was fixed, and the humerus was fully rotated on its long axis in the glenoid cavity, and then carried, in a series of short jerks, through all its natural range of movement. Numerous adhesions around the joint were felt to give way. He now lost much of his pain, and could move his arm freely except in an upward direction. A fortnight later the arm was carried, while he was under gas, freely above his head; after this all his pain ceased and he recovered the full use of his limb.—No. 2. A man, aged twenty-four, in jumping from a cart twisted his foot under him. Great pain and swelling followed, and the limb from the instep to the middle of the calf came out, he said, "all black and blue." He was laid up for a fortnight, and then took to walking with a stick. Eight months afterwards he came to St. Bartholomew's Hospital. The joint was still swollen, and the seat of severe pain if weight was thrown upon it. He had gone from hospital to hospital and been liberally supplied with bandages, elastic stockings, liniments, and the inevitable tincture of iodine; but he got no better. The ankle was found free from unnatural heat, indeed it was unnaturally cold; the skin was bluish and shiny, and the outlines of the joint were obscured by brawny swelling. The heel was a little drawn up, and flexion and extension were almost entirely lost. He took gas, and the joint was carried by short jerks through all its natural range. Numerous adhesions in the sheaths of the surrounding tendons were felt to give way. Within an hour he walked freely about the ward, and the next morning walked from Hackney to the hospital and reported himself ready to go to work on the limb. Six months later he came with the ankle again out of order. He said he had been quite well till three months before, when the joint had become painful and weak. On inspection, nothing could be found amiss, and he was advised to have the part strapped, and to rest it. He however said he was sure if it were "bound" it would be all right. Gas was given, and the joint was carried into full extension and full flexion. During flexion some slight adhesions were felt to give way. He wrote next morning to say that he had been walking on the limb, and found that he could now do so without either pain or limping.—No. 3 was a case of a similar character. A man, aged forty-five, could bear no weight on his ankle nine months after a severe sprain. The joint was quite free from heat. All his symptoms disappeared when the ankle was flexed and extended under gas; and in less than a week he was quite well.—No. 4. A lad, aged seventeen, of strumous family, was reported to have hip-disease. He could bear no weight on his limb, and the thigh was flexed, abducted, and rotated outwards. There was deep-seated pain at the back of the joint on any movement, and tenderness on pressure in this situation. There was no swelling. On examination, it was found that the hip-joint was sound, but it was believed there was strumous periostitis of the innominate bone beneath the external rotator muscles. He was told to rest, to have a course of blisters, and to take cod-liver oil. Three months later, as he was no better, he was taken to a bone-setter, who moved his limb. After this he lost all his pain, and in a week was "all right." Just twelve months later, having in the interval been quite well, he was, on rising quickly from his chair, seized with his old trouble. He had great pain, and felt sick, and the limb became instantly locked and intensely painful, if any weight

Digitized by Google

was thrown upon it. On examination, the thigh was found flexed, abducted, and rotated outwards; movement at once produced painful spasmodic contractions of the muscles, and there was excessive pain on pressure over the sciatic notch. He was put under gas, and the limb was gently carried through its complete range of flexion, extension, abduction, adduction, and rotation. Directly afterwards, though nothing seemed to give way, or to slip, he lost his pain, and he could freely move his limb. He has had no relapse. Mr. Marsh remarked that he had brought the subject of bone-setting forward because, undoubtedly, there were a numerous set of cases which forcible movement could speedily cure, but which had not hitherto been treated as commonly as was desirable by this means. These cases, as they made but little progress under the routine treatment of rest, liniments, and elastic stockings, frequently fell into the hands of bone-setters, by whose manipulations many of them were cured. He alluded principally to cases in which adhesions had formed in or around joints, otherwise sound, as the result of injury or inflammation. Sir James Paget was the first to draw attention to this subject in a clinical lecture given as long ago as 1867, and since published in the first and second editions of his Clinical Essays and Lectures. In this essay the principles of forcible movement as a means of treatment were very clearly and most fully laid down, and were rendered all the more distinct by being brought into contrast with those which regulate the use of perfect rest so essential for joints which were the seat of inflammation, especially of strumous disease. Displacements of cartilages and slipped tendons might be, and doubtless sometimes were, put right by bone-setters; but he believed the cases of adhesions — especially such as occurred after an injury outside a joint, which itself was healthy,—afforded by far the most numerous instances of improvement after forcible movement, and he expressed his conviction that they were much more frequent in practice than many had supposed. After referring to the classes mentioned by Dr. Hood in his lectures, the author stated that all he had observed led him fully to accord with the teaching of Sir James Paget, that when joints after injury have remained stiff, "weak," and painful, and yet free from abnormal heat, beyond the usual period of convalescence, and when they had no history of previous disease, and when a careful examination could detect no evidence of any of the diatheses, such as struma, or severe gout or rheumatism, the patient should be put under gas, and the limb should be carried in all directions through its full range of movement. As to the movement of particular joints, the author had seen good results in the shoulder, the finger joints, the knee, and the ankle. He had not used the method in either the elbow or the hip, having met with no cases which seemed suitable for it. In conclusion, he stated that if synovitis had been present movement must be very cautiously employed. In two knee cases lately under observation, in which synovitis had subsided for eight or nine weeks, and the joints had become perfectly free from swelling and abnormal heat, a renewed attack of inflammation, with heat, pain, and considerable effusion, had followed the manipulative treatment.—Mr. HULKE said they were much indebted to Mr. Marsh for bringing this very interesting subject before the Society. It was an opprobrium to surgery that so many people sought advice from bone-setters, not that patients could be prevented from sliding away, but because it was notorious that these empirics were or are in the habit of extracting written guarantees from their patients before proceeding to interfere with them; and thus the bone-setter, having shielded himself from the possible event of malpraxis, promises everything. To show how even intelligent people are blinded by the statements of these men, Mr. Hulke mentioned that he was consulted by a lady who had an enlarged bursa over the ischial tuberosity—a stiff hip-joint compelling her always to sit sideways on her chair. He explained the nature of the case, but the patient was persuaded to go to a bone-setter, who, after giving her oils for inunction, proceeded to put the "bone" in, which he did so effectually that the patient's husband declares that he "saw it go in!" He had no doubt some of the cases treated in this way were instances of adhesions, as Mr. Marsh had said, and the occurrence of such adhesions was long ago pointed out by Bonnet of Lyons. He (Mr. Hulke) had been personally the subject of such a condition. When in the Levant he fell over some rocks and injured his knee, which became acutely inflamed. The acute attack passed away, and left him with a stiff joint, so that he could not walk without support. Falling one day, his knee was bent under him, and, as he supposed, the adhesions must have given way, for on rising he found that he had regained free use of the joint, and could walk well without his supports; so that he thought there were such cases, which admitted of rapid cure when there was no actual disease of the joint. But, he added, we hear only of the benefit done by "bone-setting"; its disasters are carefully concealed. He had seen such disasters—often very grave mischief indeed; and more than once he had to excise a joint damaged from the rough usage it had suffered. One case he knew of, where there was disease of the shoulder and sinuses around the joint; the bone-setter broke down the adhesions, rekindling the inflammation, and the result was the death of the patient. If such cases could be published in their bare truth, the law would hardly shield the author from libel.—Mr. JOHN WOOD said there were cases in which the adhesions were outside the joint, especially the shoulder. A blow or injury on the deltoid was apt to be followed by great pain, lasting for months or even years. In such cases forcible movement was most successful, and the interpretation was that the subdeltoid bursa was inflamed and adherent to the muscle—a condition he had often found on dissection. Such cases were cured by manipulating the limb in different directions, or by acupuncture. But occasionally, after temporary relief, the pain returns. Where the articular cartilages are the seat of adhesions, such manipulative treatment was less likely to be permanently successful. Some of the cases of so-called misplacement of tendons were, he thought, really instances of inflammations of the sheaths of the tendons. The case which Mr. Marsh thought was one of displacement of the obturator tendon, was more likely an instance of effusion into the bursa in this situation; for it was difficult to see how the tendon could slip out of its groove; and the procedure adopted probably caused the rupture of the enlarged bursa. He had seen great mischief due to bone-setters, and this mainly in cases of hip disease; and he would warn surgeons in such cases of the impropriety of attempting too early movement, lest inflammation of the bone be again set up. He had thus seen very serious symptoms started by movement attempted twelve months after the primary inflammation had subsided. In old subjects, with tough and extensive adhesions, he had repeatedly seen fracture take place from the attempt to break down adhesions. "Sudden jerks," then, were to be deprecated; but gentle and slow movements, gradually increased in range, should be the plan followed. Not long ago he saw a lady who had anchylosis of both knees from rheumatism. Gentle manipulations succeeded in breaking down the adhesions in one knee; but in the other (which was more firmly anchylosed) the ligamentum patellæ gave way. The smooth porcellanous character of the ends of the bones, denuded of cartilage, could be felt; and in so advanced a case he was sure breaking down the adhesions did but little good. The ruptured ligamentum patellæ healed, but the stiffness returned to the joint. There was another class of cases out of which bone-setters made much capital—viz., cases of "hysterical spine"—of which he related an instance where a bone-setter, pretending that the patient had twisted her spine, proceeded to manipulate, and cured the patient at least for some months of the pain from which she had long suffered. It was just possible, of course, that in that case one of the little interspinal muscles had been displaced, and that it had been reduced by manipulation; but he was inclined to think that in the majority of cases hysteria was the real cause of the pain, and that the cure was attended by the deception of the patient on the one hand, and the bone-setter on the other.—Mr. T. SMITH asked whether Mr. Marsh advocated these measures for the relief of stiffness in a limb following union of fractures. He was inclined to believe, with Mr. Wood, that adhesions were often outside a joint, and he had followed the procedure in desirable cases of the class pointed out by Sir James Paget, Mr. Wharton Hood, and Mr. Marsh. In six cases of Colles' fracture at periods varying from six weeks to three months, where the fracture seemed to have united badly, he had broken down adhesions of tendons by free and forcible movement. In no case had any serious disturbance followed; in two or three the manipulation was repeated more than once, and was followed up with shampooing and friction. In one case, where the whole hand was stiff, he began by liberating two fingers, and then passed to the others, taking each in turn. The same methods were applicable to the after-treatment of other fractures—e.g., of thigh and leg; in the former case the knee, and in the

Digitized by Google

latter the ankle, could be set free by forcible movement from the stiffness (and in the case of the ankle the malposition) so often following fractures. He agreed with Mr. Wood as to the improbability of one of the rotator tendons of the hip slipping out of place, for its anatomical disposition hardly showed where it could slip to. But no more could he see how an interspinal muscle could be displaced.—Mr. HEATH endorsed Mr. Smith's remarks as to the after-treatment of fractures. No fracture should be considered cured until the movement of the joint was completely restored; and were this thoroughly appreciated, many a case would be taken out of the hands of the bone-setters. The same thing applies especially to cases of injury about the shoulder. The pain, &c., were generally left to time, but in his opinion time never does cure them, and it was to be regretted that some of the most eminent surgeons should take the former view. Many such cases were set right by manipulation under anæsthetics. Whether there were adhesions inside or outside the joint was an open question. In some cases—e.g., the knee—they were certainly within the joint. In breaking them down often decided loud "cracking" sound was produced, but this must not deter the surgeon. He had once fractured a humerus in this manipulation, but after union had taken place the patient was better than before. Of course, care must be exercised in the case of old people.—Mr. BARWELL thought cases of slight subluxation, such as occurred in the shoulder and ankle, should not be overlooked. He had seen cases of injury where there were no ordinary signs of dislocation or inflammation, yet there was inability to raise the arm; and a slight manipulation under nitrous oxide would often put them right, so that in many cases the use of the arm was immediately regained. The same held good with the ankle and tarsus, where a condition of slight downward luxation of the scaphoid produced lameness and inability to bear the weight of the body on the foot. He thought there was also a condition of subluxation of the os calcis on the astragalus. He had met with displaced tendons about the malleoli, especially the peroneus longus tendon; although the tendon could be replaced, it was almost impossible to keep it in position. He mentioned an instance where a lameness was cured by manipulation, which reduced a tendon so misplaced; but in another case no device succeeded in keeping the tendon in its groove. He asked what was meant by adhesions within a joint. He had never seen on dissection any adhesions comparable to those of other serous membranes; but hypertrophied synovial fringes might become united, and he had seen union between two cartilages on the knee. He concluded by relating how a lady who was thrown down by a cab, and seen by a bone-setter, who declared a "bone was out," and after manipulation said she was cured. But the reverse was the case, for in addition to a dislocation of the hip, she had also a fracture of the neck of the thigh, probably produced by the manipulation referred to.—Mr. G. BROWN, referring to cases of anchylosis after acute rheumatism, said that owing to wasting of the muscles from impossibility of having early recourse to movement, the patient was unable to move the joint, although this may have been set free by passive motion. What procedure should be adopted in such cases, of which he had recently had an example under his care?—Mr. MORRIS said the debate suggested that it was not well to draw too much distinction between adhesions formed outside or inside a joint; but there were cases—e.g., in shoulder and knee—where the contraction was due to changes in the capsule of the joint itself. He had dissected a contracted knee-joint, which could not be straightened until after division of the posterior ligament. So, again, in the shoulder there might be contractions and adhesions in the capsular ligament itself. If such structures be ruptured in attempt at restoring the limb the relief could only be temporary. He asked whether it was justifiable within six or seven weeks of the injury to resort to passive movement for the relief of stiffness due to fracture of the olecranon or patella. A recent case had brought this to his mind. A gentleman broke his olecranon by a fall on the ice, and a second injury delayed union. At the end of six weeks he became impatient to use the arm. Mr. Morris was averse to moving the limb too early. A further opinion was sought, which was favourable to forcible flexion under chloroform. This broke down the fracture again, and set up inflammation of the joint.—Mr. PRESCOTT HEWETT, who spoke on the invitation of the President, said that no doubt the cases in which the bone-setter succeeds were of the class alluded to by Messrs. Heath and Smith—viz., a slight injury followed by some contraction about a joint. The knee was often the seat of this, where, as in Mr. Hulke's case, an acute synovitis was followed by lameness due to adhesions, which could be readily broken down by forcible movement. He had broken down adhesions in knee and ankle with great benefit; he had been less successful with the shoulder, and least of all with the elbow. He found that Sir James Paget and Mr. W. Hood were of the same opinion as to the slight results following such treatment of the elbow—which is often the seat of adhesion—especially after fractures of one or other condyles. He had practised forcible movement under chloroform to break down the adhesions found in connexion with contracted toes, due to wearing short and narrow shoes, such contractions occurring often after the foot had been cramped for a very short time. Some of the cases consulting bone-setters were no doubt instances of slipped tendon; he had seen this occur in the case of the biceps tendon, and in those of the peronei muscles—these being difficult to maintain in proper position. No doubt great injury is at times done by too forcible measures employed at too early a period. He was once present when manipulation employed to break down adhesion about the hip resulted in fracture of the thigh, and that in a powerful young officer. He had seen severe inflammation follow attempts to break down adhesions of the knee-joint; and in one case pyæmia followed such an attempt made on the shoulder. The worst example he knew of the injury done by bone-setters was in the case of a young gamekeeper, whose leg became inflamed and gangrenous, following the manipulations of the bone-setter. The thigh had to be amputated, and the patient died.—The PRESIDENT expressed the hope that the discussion would bear fruit; not that it would prevent people going to bone-setters, but that it would enable surgeons to lay down the lines of the scientific treatment of such cases, and show their country friends that such cases were understood and could be rationally dealt with. Quite lately a friend of his, the subject of hysteria only, fell into the hands of a bone-setter. Of course, it could scarcely be expected that surgeons would do all that the bone-setter proposes to do—they are more cautious than the latter, to whom the adage, "Fools rush in," &c., would well apply.—Mr. MARSH, in reply, said that in relieving the stiffness of a shoulder it was essential to fix the scapula, which otherwise accompanied the humerus in its movements. The sudden event of the pain and lameness, and the rapidity of its cure in his fourth case, made him attribute it to slipping of the obturator internus tendon over a ridge of cartilage. He agreed with Mr. Wood that the jerks should be slight, and he had seen cases where too much force had been used and the thigh fractured. To Mr. Barwell he said that he had seen actual adhesions in joints; and he agreed with Mr. Morris that contraction of the ligaments was likely enough to occur in severe cases.

Reviews and Notices of Books.

A Treatise on Hygiene and Public Health. Edited by ALBERT H. BUCK, M.D., American Editor of "Ziemssen's Cyclopædia of the Practice of Medicine," Instructor in Otology in the College of Physicians and Surgeons of New York. Two vols. large 8vo; pp. 792 and 657. New York: Wm. Wood and Co. London: Sampson Low, Marston, and Co. [SECOND NOTICE.]

THE second volume is divided into two parts, one relating to Occupation, the other to Public Health.

The first part is subdivided into five sections, dealing respectively with the hygiene of occupation, the hygiene of camps, the hygiene of the naval and merchant marine, the hygiene of coal-mines, and the hygiene of metal-mines.

"The Hygiene of Occupation" is from the pen of Dr. Roger S. Tracy, sanitary inspector of the Board of Health, New York. It is a very complete statement of the health-conditions involved in various kinds of occupation. Dr. Tracy divides occupation into three principal classes—namely, occupations involving the introduction of deleterious matters into the body; occupations involving exposure to conditions that interfere with nutrition; and occupations

Digitized by Google

involving exposure to mechanical violence. He distributes the various occupations in these several classes, and presents an admirable summary account of existing knowledge of their hygiene enriched by his personal experience on the subject.

"The Hygiene of Camps" is written by Dr. Charles Smart, C.M., Assistant-Surgeon U.S. Army. This article should be particularly welcome to the medical staff of our volunteer forces, and, indeed, to military medical men in general. The illustrations of Dr. Smart's subject, taken from the experience of the war of secession, are peculiarly instructive. We would especially note his observations on overcrowding in tents, on tent-hygiene, on hut-construction, and generally on the hygiene of camps and the camp kitchen. The article is a real acquisition, and it gives special consideration to the camps of civil life as well as of military life.

Dr. Thomas J. Turner, M.A., Ph.D., Medical Director of the United States Navy, has written the section on the "Hygiene of the Naval and Merchant Service." It is almost superfluous to say that it contains the result of much and extended experience effectively put together. It is remarkable how barren English literature is of works on the hygiene of a service which has been made so peculiarly a service of English-speaking people. This section forms a very welcome addition to our scanty literature on the subject.

"The Hygiene of Coal-mines" is from the pen of Mr. Henry C. Sheafer, the coal editor of the *Miners' Journal*, Pottsville, Pa., and the "Hygiene of Metal-mines" from the pen of Mr. Rossiter W. Raymond, Ph.D., editor of the *Engineering and Mining Journal*, New York City. Both are excellent articles, full of valuable information.

The second part of the volume, relating to Public Health, is divided into eleven sections, which we shall briefly note in the order of their occurrence. "Infant Mortality and Vital Statistics," by Dr. Thomas B. Curtis of Boston, Mass., is an elaborate article, of which the part relating to infant mortality has much to interest the English reader. "Adulteration of Food" is dealt with by Mr. Stephen P. Sharples, S.B., of Boston, Mass. It is a capital summary article on the subject. "Public Nuisances" are treated by Dr. Roger S. Tracy in the widest sanitary sense. He regards as a public nuisance "anything that injuriously affects the health or comfort of the occupants of two or more premises other than the premises on which it exists," and upon this text he has written an exhaustive treatise. "Quarantine" (with reference solely to seaport towns) forms the subject of an article by Dr. S. Oakley Vanderpoel, LL.D., health officer of the port of New York; and "Inland Quarantine" the subject of an article by Dr. J. J. Hawick, secretary of the Louisiana State Board of Health. Both articles will be read with much interest in view of the opinions as to quarantine entertained, and action taken, by the National Board of Health. "Small-pox and other Contagious Diseases" are considered in their hygienic relations by Dr. Allan McLane Hamilton of New York, in conjunction with Dr. Bache McE. Emmett. "Disinfectants" are treated by Mr. Elwyn Waller, Ph.D., chemist to the Metropolitan Board of Health, New York. "Village Sanitary Association" (an article of great interest), by Dr. Roger S. Tracy; and an article on "School Hygiene," by Dr. D. F. Lincoln of Boston, Mass., closes the volume.

We have thus cursorily glanced at the contents of these two volumes. It will be obvious, even from this imperfect account of their general character, that the work must take a very important place among standard treatises on hygiene and public health. There is a surprising uniformity of excellence throughout the numerous articles of which the book consists, and we apprehend that it will become a favourite one for reference. It is clearly a work which will be more highly valued the more closely it is studied. To say it is worthy of the country of its origin is to say a great deal, but not more than is deserved. Dr. Buck has achieved the heavy task he undertook, of organising the arrangements for and editing the work, with singular success.

The Atlas of Histology. By E. KLEIN and E. NOBLE SMITH. Part X. Plates xxxiv—xxxvii. London: Smith, Elder, and Co. 1879.

THIS part embraces accounts of—1. The small and large Intestine. 2. The Pancreas. 3. The Liver. 4. The Larynx and Trachea, and the Bronchi and Lung,—all subjects of much interest. Dr. Klein supports Dr. Watney's view that the absorption of chyle, or perhaps, more correctly speaking, of chyme, takes place through the interstitial tissue between the cells covering the villi, and not through the cells themselves, so far at least as the mammalia are concerned. The question of the origin of the bile-ducts seems to be still a little doubtful. After describing the bile-ducts down to the margin of the lobule where they are much branched, communicate with each other, and are lined with a single layer of more or less flattened epithelial cells, and constitute the intermediary portion of the duct, the authors give the following account of the further course of the ducts: "The intermediary portion of the bile-ducts joins the substance of the lobule in this manner: the lumen of the former passes directly into the network of bile capillaries, while the flattened epithelium, changing of course suddenly its appearance and nature, forms a direct continuity with the mass of the liver cells. The membrana propria is not continued into the lobule on to the surface of the liver cells, as is maintained by Beale, Pflüger, and others." This view is not altogether in accordance with the statements of recent writers, some still holding that the minutest ducts have a membrana propria.

We notice a few clerical errors:—"Latchenberger" should be Latschenberger, "Chrzonszewski" Chronszczewski, and "Fry" Frey. In the following sentence "take up" is an incorrect expression:—"The interlobar connective tissue contains nerve branches and large lymphatics with valves. These latter take up lymphatic clefts and sinuses," &c. The meaning probably is "receive the contents of." The drawings are, as usual, extremely carefully and accurately drawn, and in delicacy of execution the plates of this part surpass those of the preceding.

Diseases of the Ear. By GEORGE P. FIELD, M.R.C.S., Aural Surgeon of St. Mary's Hospital, and Lecturer on Aural Surgery in the Medical School. Second Edition. London: Henry Renshaw. 1879.

THIS book is worthy to have reached a second edition in a very short time, as it has done. It is not pretentious or exhaustive, but it will be found to be very practical and helpful to the student and to the general practitioner. The three opening chapters are taken up with, respectively, the anatomy of the ear, the physiology of hearing, and the examination of the patient. Chapter 4 contains some very practical observations on affections of the external auditory meatus, and especially on the proper way of removing foreign bodies, which may be read with much advantage. Mr. Field very properly recommends the use of the syringe in preference to that of forceps and other instruments. Thereafter follow eleven other chapters dealing with all affections of the ear, and, at most length, with the commoner ones, all of which are enriched by good, though short, clinical reports of illustrative cases. A noticeable feature of the book is a number of coloured illustrations, the work of Mr. E. Noble Smith.

Mr. Field mentions the frequency with which acute catarrhal inflammation of the ear is overlooked until a discharge from the ear is noticed. It is well, when we cannot find other reasons to explain fever and restlessness and crying in a child, to suspect otitis; and we shall be

Digitized by Google

helped in forming a judgment by seeing whether the little patient refuses steadily to lie on one side, which Mr. Field says he invariably does in this affection. This is a good hint, like many others, obtained from a doctor's close observation of his own child. We can commend this book to practitioners and students.

Du Traitement Mécanique des Maladies de la Colonne Vertébrale par l'application des Corsets Plâtrés. Par OSCAR JENNINGS, M.D., M.R.C.S.E. Paris: O. Berthier. 1880.

THE treatment of curvature of the spine by "plaster-of-Paris jackets" applied during extension has not been received with so much favour, or so widely adopted, in Paris as in England and on the Continent generally. Dr. Jennings is a warm advocate of this treatment, and is anxious that Sayre's method should have a fairer trial at the hands of the profession in Paris than has yet been accorded to it. He accounts for the prejudice existing against it in France, by stating that in attempting to carry it out the French surgeons have wilfully neglected the details upon which Sayre justly lays so much stress; and he avers that the proper muslin for the bandages cannot be obtained in Paris. If this be the case, we are glad that there is at least one surgeon in Paris who is engaged in carrying out Sayre's treatment in accordance with his directions, and who, happily, is meeting with Sayre's success. The paper now published in a pamphlet form originally appeared in *La Tribune Médicale*, and we confidently expect that its wide circulation will lead many to reconsider their present convictions, with a very happy result for their patients.

THE INDIAN MEDICAL DEPARTMENT.

THE following General Order has been issued for the regulation of the administrative branch of the Indian Civil Medical Service:—

1. In continuation of General Order No. 13, dated Jan. 2nd, 1880, issued in the Military Department, and subject to such modifications as may hereafter be deemed necessary, the Governor General in Council is pleased, with the sanction of Her Majesty's Secretary of State, to issue the following orders regarding the administrative staff of the Indian Medical Department in the several provinces of India.

2. From the 31st March, 1880, the following administrative appointments will be made:—

	Monthly Salary. Rs.
One surgeon-general with the Government of India...	2700
One deputy surgeon-general, with local rank of surgeon-general, for civil medical administration in Bengal	2250
One deputy surgeon-general, with local rank of surgeon-general, in the North-Western Provinces and Oudh	2250
One deputy surgeon-general, with local rank of surgeon-general, in the Punjaub	1800
One deputy surgeon-general for civil medical administration in the Central Provinces	1800
One surgeon-general for civil medical administration in Madras	2500
One secretary to the surgeon-general, Madras... ...	800*
One surgeon-general for civil medical administration in Bombay	2500
One secretary to surgeon-general, Bombay	800*

* Consolidated.

3. The surgeons-general with the Government of India and with the Governments of Madras and Bombay will, in addition to performing civil administrative duties, be heads of the Indian Medical Departments in their respective Presidencies. It will be their duty, among other matters, to propose transfers between the Military and Civil Departments; to recommend for promotion to the administrative grades; and to advise the Government on all questions relating to the admission of officers and subordinates to the Indian Service, to the conduct and services of Indian medical officers of all grades, and to the supply of medicines and hospital stores. The surgeon-general with the Government of India will be entitled to receive any information he desires from the surgeons-general and deputy surgeons-general attached to the Local Governments and Administrations; but he will exercise no direct authority over them. These officers will be solely under the orders of the Local Government or Administration to which each belongs.

4. Officers will be selected for the above-named administrative offices by the Government of India for the Bengal Presidency and by the Governments of Madras and Bombay for those Presidencies respectively. Selections will be made in each Presidency from the whole Indian Medical Service of that Presidency; and the principles of selection, hitherto followed in making such appointments, will be observed. Surgeons-general and all deputy surgeons-general, including those who may have the local rank of surgeon-general, will count their five years term of office from the date of their first entering on the duties of their rank, whether in the military or civil branch of the service.

5. The deputy surgeon-general for the Central Provinces will also be sanitary commissioner for those provinces. As already notified in the Military Department Order above quoted, "the deputy surgeons-general of the Eastern Frontier District and of the British Burmah Division will, in addition to their military duties, exercise the civil medical administration of their respective provinces, and will also perform the duties of sanitary commissioners in them." The deputy surgeons-general of the Punjaub Field Force, and of the Scinde District, will also exercise the civil medical administration of those circles. In respect of these civil duties they will be subject to the orders of the provincial surgeon-general.

6. In all provinces for which a separate sanitary commissioner is sanctioned the sanitary department will remain distinct from, and not subordinate to, the medical department. The Sanitary Commissioner of Madras and of Bombay will, in future, have the rank and privileges of a deputy surgeon-general, as soon as he attains twenty-six years' service, or as soon as any officer below him on the list is promoted to the administrative grade; and, subject to the same conditions and limitations, the Sanitary Commissioner of Bengal, the North-Western Provinces, and the Punjaub, will have the rank, pay, and privileges of a deputy surgeon-general. This rule will apply to officers now holding the appointment of sanitary commissioner in these provinces. The five years' tenure of office by a sanitary commissioner in each province will reckon from the date of his attaining the rank and privileges of a deputy surgeon-general. In the appointment of officers to be sanitary commissioners the same principles and procedure will be adopted as in the promotion to deputy surgeon-general in the military and civil administration; but in the selection for such posts knowledge and experience as a sanitary officer will be specially considered.

7. The supervision of the Vaccination Department will form an important part of the duties of the sanitary commissioner in each province. The separate appointment of superintendent-general of vaccination, where it still exists, will be abolished, and this officer as well as the superintendent of vaccination will become a deputy sanitary commissioner under the orders of the sanitary commissioner, who will utilise not only them, but also the whole vaccination staff and the civil surgeons as far as possible in sanitary work.

8. Although the administration of the Indian Medical Department is divided into two branches—civil and military—Indian medical officers will remain as now, military officers, those in civil employ being only lent to the Civil Department, and liable to be called on for military duty in the event of their services being required.

9. Officers holding appointments which are abolished under these orders—viz., the superintendent-general of vaccination, Punjaub, and the sanitary commissioners for the Central Provinces and British Burmah—will receive a personal allowance, making the emoluments of their future offices equal to the pay they now draw.

AN application has been made by the local sanitary authorities of Bournemouth for a provisional order to enable them to purchase compulsorily five acres of land, whereon to erect a fever hospital. The building is estimated to cost from £6000 to £8000.

THE LANCET.

LONDON: SATURDAY, APRIL 17, 1880.

A NEW Parliament raises new hopes; and this irrespective of political bias, from which we are of course quite free. It would be a sad thing to believe that great political conflicts, and even great political reverses, had no good in them. Tired men get at least a period of repose. They see wherein they have disappointed public expectation and failed to realise their own promises; and another set of men, who have had the advantage of studying all their errors and the enjoyment of a period of rest, come into power. It would almost seem as if legislation nowadays was too arduous and many-sided a business to be conducted by one set of men. Lord BEACONSFIELD is too great a man not to indulge in reflections on the lessons of the election which is now wellnigh over; and though, like other moralists, he may put much down to popular fickleness, he is too wise not to perceive that in the judgment of the country there are some elements of justice. He would probably admit that the domestic legislation of this country since 1874 has been very unsatisfactory: first, that there has been very little of it; and, secondly, that this little has been weak and ineffective. There has been some excuse for this state of matters in the urgent foreign questions which have arisen since the last general election; but the urgency of foreign affairs has not been such as to afford an excuse for a Ministry so powerful as this has been doing so little to promote the domestic welfare of the nation. Both political parties need the lesson which the election teaches. It is amazing how little the keen politician of either side cares for quiet questions of domestic policy—for measures that will make health more secure, and so make life brighter and happier. Take, for example, the question of the water-supply, which has been disastrous to the present Government. It is to the lasting disgrace of both parties in the State that four millions of people have been allowed up to this time to remain at the mercy of grasping companies in the matter of a commodity as needful as light and air, and have had to put up with a short and intermittent supply of comparatively dirty water, for which they have had to pay very dearly. Though the Government cannot be congratulated on its actual proposals for dealing with this question, it is at least entitled to credit for being the first Government to perceive that the water-supply of four millions of people is a question of State magnitude, and as worthy of the attention of a strong Cabinet as the stipulations of a European treaty. Mr. CROSS may comfort himself with reflecting that he has at least raised the question out of its parochial and commercial relations into the category of those subjects which need a statesman's care.

It will be the fault of the next Government if they do not show a very considerable enlargement of view as to the duties of the State. It is to be hoped, too, that we shall see the end of that curious phenomenon "permissive legislation." Let us have either law or freedom. We can understand one or the other, but not the hybrid weakling which is neither one thing nor the other. Where there is no urgent need for restriction of personal action let us have no legislation. Where personal action is used to the disadvantage of dozens or scores of others, by all means let us have law that will powerfully and directly control personal freedom used so selfishly and injuriously. To give a habitual drunkard who is drinking himself and his family into the workhouse and into the grave, "permission" to go into a retreat for curative purposes, is to bring law itself into disrespect, and it is not very much otherwise to give rival examining boards "permission" to combine to form one board, or rate-sparing vestries in their capacity as sanitary authorities, "permission" to make—or not to make—provision for an outbreak of deadly disease. We want the *minimum* of law; the less of it the better, but that little should be strong and effective.

We venture to hope that the new Parliament, and the Government that is to be, will not be behindhand in dealing thoroughly with those great questions of public health which have so much to do with public virtue and happiness. As regards the composition of the new Parliament we shall greatly miss some whom we have ever found helpful and sympathetic. Amongst the members of our own profession whose services in past Parliaments have been most useful, but who are to be allowed to rest, we cannot forget Dr. BRADY and Dr. LUSH. We owe to Dr. BRADY the Act which secured retiring allowances to Poor-law medical officers who spend the best part of their life in the service. And we owe much to Dr. LUSH for his interest during the last twelve years in every question affecting the efficiency and honour of the profession, and, very particularly, the prevention of premature medical legislation, and the thorough representation in successive medical Bills of the questions involved in medical reform. It cannot be doubted that the new Parliament will revive the Select Committee for inquiry into this subject, but we regret to think that it cannot have the presence of Dr. LUSH, and that both Mr. ARTHUR MILLS and Mr. WHEELHOUSE, good medical reformers, will be conspicuous by their absence. The other members of the Committee are either returned or likely to be returned. Mr. MITCHELL HENRY, Dr. CAMERON, and Sir J. T. LAWRENCE have already secured their seats.

There is no reason to think that a Liberal Government will be indifferent to the settlement of this subject. Mr. FORSTER has taken great personal pains to master its details, and the Marquis of RIPON is known to feel very strongly as to the importance of non-permissive legislation for the consolidation of the Examining Boards. He used to be of opinion that this part of the question could be dealt with separately from the constitution of the Council; but the course of events has ruled otherwise, and we may now hope for the help of a new Ministry in passing a great and lasting measure of medical reform.

We are pleased to notice the return of several members of the profession for the first time to Parliament, amongst them Dr. ROBERT FARQUHARSON, of Brook-street, for West Aberdeenshire, and Dr. ROBERT DYCE LYONS, of Dublin. Both these gentlemen are hospital physicians. They are graduates, respectively, of Edinburgh and Dublin, and we

Digitized by Google

are sure they can be relied on faithfully and intelligently to represent the views of medical citizens in Parliament.

THE suggestion that the office of President of the Local Government Board should be given to a prominent member of the in-coming Ministry, and that he should be provided with a seat in the Cabinet, is so important, that we make no apology for reverting to it. There has long been a growing sense of the need which undoubtedly exists for an ample and practical recognition of the interests and principles of Public Health as an integral part of State policy. Not only do questions of a specifically sanitary character demand broader and clearer views from the supreme government stand-point; Health, as a factor in progress and as an element of prosperity, requires to be constantly represented in the innermost council of the State, where policy is shaped and the balance between those diverse and often conflicting interests which are likely to be disturbed by any new measure is adjusted. It is too much to hope that Health will ever be represented directly in a Cabinet, but nothing short of representation of some kind in that conclave will satisfy the necessities of the case. It, then, only remains to ask that the particular member of the Government who is officially charged with the control of the public health officers of the country, may be admitted to the position his office claims.

Even if the Health question were not involved in this proposal, there would seem to be cogent and strong reasons for making the claim we urge. The President of the Local Government Board is, in a *political* sense, one of the most important members of the Government. He is, in a very special way, the connecting link between the country as a whole and the Ministry. The Secretary of State for Home Affairs may guess the state of local feeling, but the President of the Local Government Board *knows*, or ought to know, how the population is affected in its localised opinion and enterprise. The fundamental principle of constitutional rule in England is self-government. The President of the Local Government Board is, so to say, the Moderator placed at the head of the multitude of local incorporations of this constitutional idea. The Government, properly so called, is the aggregate and concentration of the self-governments of the nation. These are localised, each district being a state or commune for domestic purposes, and yet the President of the Local Government Board—or the Central Board of the local governments, as it might well be called—is not in the Cabinet! He ranks as a subordinate official, although he, and *he alone*, is the embodiment of the great constitutional principle.

The Secretary for Foreign Affairs is a Minister told off to keep the outside enemies of the country in check, and to assert the international interests of the State. The Secretary for War and the First Lord of the Admiralty are the champion knights of the kingdom acting under the Secretary for Foreign Affairs. The Treasury, the Exchequer, the Home Office, are departments designed for the administration of general business. Not one of these ministries is so directly and peculiarly *representative* as that of the Local Government Board. Probably it is on this very account the President of this department stands so low in the ranks of administrators as to be universally excluded from the council of supreme government. The theory of the Cabinet doubtless is that it should be composed exclusively of representatives of the Sovereign, not of the people! The time has arrived when this senseless tradition should be broken through, and we venture to hope the party which is about to grasp the reins of government will not hesitate to take a step urgently necessary in itself, and sure to be approved by the people. There is nothing unconstitutional in the proposal we now make, though for party purposes, or as a plea for delay, it may be so represented. There could be nothing derogatory to the dignity, still less even approximating an infraction, of the Royal prerogative, in the admission of a representative of self-government to the rank of a Minister. We contend that it would strengthen the stability of the Throne to introduce a Minister into the Cabinet who should be able to give prominence to the wishes of the population as expressed in the local corporations, and whose bearing and actions towards these local corporations should be in a practical sense ministerial and representative of the Crown by something approaching a direct delegacy.

Either the suggestion we have thrown out will be unheeded by those for whose consideration it is intended, or objections will be raised. It has scarcely ever happened that a recommendation made as this has been made produced an immediate effect. That the time will come when it must be adopted we cannot doubt. It would be a graceful concession to the desires of a profession which has been much neglected of late, and a timely recognition of public expediency, if the arrangement proposed were at once carried out. Without a seat in the Cabinet no President of the Local Government Board can hope to grapple effectually with the daily increasing difficulties of the office, and no really strong and able statesman will accept the position unless he is allowed to rank as a Minister. Some step must be taken in this matter before any considerable time elapses, and probably a remedy would have been devised before this but that a most absurd arrangement stops the way. The Lord President of the Council, apparently to make business for that august but not very useful Minister, has been entrusted with certain duties which do not belong to his office traditionally, or, so far as we can see, arise out of its historic functions. If, for example, a plague to man or beast afflicts the country, the Lord President is the dignitary to put it down, although as a matter of fact, if the infliction be human the President of the Local Government Board is the only official who *can* deal with the question practically, simply because the local authorities are under his direct control, and he has his officers of health everywhere; or, if the plague be one affecting cattle, it falls to the Veterinary Department to deal with it! In no case has the Lord President of the Council either the practical knowledge, the machinery, or the local authority indispensable for a powerful effort to stamp out an epidemic disease, or carry into effect a measure of local sanitary reform. Already there have been signal instances of seeming clumsiness and complete failure on the part of this Minister, not the effects of personal inefficiency, but arising out of his official impotence. At best he can only meddle and muddle in sanitary affairs. And in any emergency his interference, or the necessity of appealing to the Lord President for authority, might be productive of the gravest consequences. Prudence requires

that an end should be finally put to this state of matters. The whole difficulty would be speedily removed if the President of the Local Government Board were admitted to the Cabinet, so that the two Ministers might rearrange their several duties and responsibilities. As it is, we greatly fear the petty jealousy of any duke who may be appointed to the office of Lord President of the Council will militate against the introduction of the nominally subordinate but practically more important administrator into the Cabinet. We point to these difficulties simply to stir the energy of some spirited and patriotic statesmen to grapple with and overcome them. That task should not be impracticable, and the moment is peculiarly well fitted for its accomplishment, while the need was never more urgent than now, or public opinion so fully prepared to endorse the change when once it has been effected.

THE General Order regulating the administrative staff of the civil branch of the Indian Medical Service has at last been published, and we think it is to be regretted that it was not brought out simultaneously with that for the military branch. Such a course would have obviated that feeling of alarm, and those expressions of discontent and anger, which were unfortunately, and, as it now seems, unnecessarily, called forth by the provisions of the first General Order. It appears that the civil medical service is to be administered by three surgeons-general, one in each of the presidencies, and four deputy surgeons-general, with local rank of surgeon-general, so that the Indian Medical Service will only lose two deputy surgeons-general by the reorganisation, and the British service has lost the same number. This loss to the Indian Service will be more than compensated by the grant of the rank, pay, and privileges of a deputy surgeon-general to each of the five Sanitary Commissioners "as soon as he attains twenty-six years' service, or as soon as any officer below him on the list is promoted to the administrative grade." The difference introduced into the system of administration by these measures appears to be that, instead of having a double staff to administer the military medical department, there will be a staff of British officers for that service, and a corresponding staff of officers of the Indian service for the administration of the civil duties. This division of duty will have the good effect of preventing any collision between the two services at times when the necessity for unanimity in action is most required, when the troops take the field. The rules hitherto in force with regard to the promotion and retirement of administrative officers in the military branch will continue in force in the civil; in fact, the medical officers are to be, as at present, military, and when on civil employment are to be considered merely as lent to the civil department, and liable to be called on for military duty when required. Three civil appointments are abolished—the Superintendent-General of Vaccination, Punjab, and the Sanitary Commissioners for the Central Provinces and British Burmah—their duties being transferred to the newly-created deputy surgeons-general; but the present holders of these appointments are to receive a personal allowance equal to the difference between the pay of the present and future officers. It will be seen that the reorganisation affects the prospects of the officers of the Indian Medical Service to a very slight extent, and there can be little doubt that with the numerous lucrative civil appointments open to them it will still continue to be the favourite service, and to command the greatest number of candidates. We speak of the service as it now exists under the rules laid down in these two General Orders. It remains to be seen whether the British Government will adopt the recommendations of the Simla Military Commission, and what effect these, if adopted, may have on the medical department; but we have not much fear of any change being introduced which will injuriously affect this very important branch of the Indian service.

WE have now before us the report[1] of Dr. AUGUST HIRSCH and Dr. M. SOMMERBRODT, who, in conjunction with Dr. B. KUSSNER of Halle, formed the medical commission sent by the German Government into the province of Astrakhan to make inquiry concerning the outbreak of plague there in the later months of 1878 and the beginning of 1879. They reached the seat of prevalence of the disease at an earlier period than the British medical commissioners (Mr. W. H. COLVILL and Dr. J. F. PAYNE), and although, like them, too late to make personal acquaintance with the disease, they were more fortunate in obtaining details as to its history, character, and progress. They had, it would appear, larger opportunity of access to documents, and of communicating with individuals who had more or less intimate acquaintance with the facts of the outbreak. This is manifest in the more elaborate description in which they are enabled to indulge, and the more precise information they afford as to the symptoms and progress of the malady. Substantially, however, they add little to what Mr. COLVILL, Dr. PAYNE, and others have made known to us of the general history and characters of the outbreak. They agree with the British medical commissioners in accepting the facts that the disease broke out in October, 1878; that it continued until the end of January, 1879; and that it appeared in six places, but in one only—namely, Vetlianka—assumed an epidemic form. But when they enter upon the discussion of the origin of the malady, they diverge in opinion from Messrs. COLVILL and PAYNE. These gentlemen were unable to accept the theory of transmission of the infection of plague from Resht or elsewhere to the banks of the Volga. Mr. COLVILL saw in the local conditions of the Volga, at the locality affected (these closely corresponding with the conditions under which plague had been observed in Mesopotamia), a source of origin; and Dr. PAYNE, while not altogether disagreeing with this view of the subject, expressed a much more guarded opinion upon it. Messrs. HIRSCH and SOMMERBRODT, rejecting the theory of local origin, are inclined to believe that the disease was brought to the Volga by infected articles of clothing carried into the district by Cossacks returning from the seat of war in Asia Minor. The difficulties in the way of accepting this theory appear to us well-nigh insuperable. The fact is, in regard to this question of origin of the outbreak, that evidence which would help to a definite conclusion is not as yet forthcoming. And this is in truth

[1] Mittheilungen über die Pest-Epidemie im Winter 1878-1879 im russischen Gouvernment, Astrachan. Berlin: Carl Heymann's Verlag. 1880.

Digitized by Google

what both the British and German Commissioners say when their words are reduced to their simplest expression. The foreign medical commissioners were on the ground too late for a successful elucidation of a question of so much difficulty, and which had to be worked out among a population whose language was unfamiliar to them, and under considerable restrictions of movement. Whether the Russian medical authorities, when their report on the outbreak is published, will be able to throw light on this subject, seems very doubtful indeed. We are thankful, however, to have in this report of Drs. HIRSCH and SOMMERBRODT, the most complete statement of the facts of the outbreak which has yet appeared. A high compliment is paid by the Commissioners to Count LORIS MELIKOFF for his energy in stamping out the relics of the plague on the Volga, but as the disease was rapidly dying away when the Russian Government first interfered for the arrest of the outbreak, it does not clearly appear that either measures of quarantine or measures of hygiene exercised any real effect in limiting the malady to the district thus infected, or in favouring its extinction.

Annotations.

"Ne quid nimis."

THE DISPUTE AT GUY'S.

IN the current number of the *Nineteenth Century*, Miss Margaret Lonsdale, the authoress of "Sister Dora," a work which has attracted a good deal of attention of late, gives to the public her version of the dispute now existing between the treasurer and the staff of Guy's Hospital concerning the nursing arrangements. In doing this, Miss Lonsdale has succeeded in widening the breach existing between the lay and medical authorities, and has given additional strength to the position taken up by the latter. Miss Lonsdale states that the medical staff are resisting the introduction of "the new system of nursing" which replaced the old system in November last. In the course of her article, contrasting the two systems of nursing, she makes the following accusations against Guy's Hospital, either directly or by implication:—

1. That Guy's has hitherto been nursed to a great extent by women of the charwoman class, into whose moral character no adequate inquiry was made, who were wholly without training in the matter of nursing, who spent their leisure time "too often, alas! in the nearest public-house," whence they returned "at the regulation hour more or less the worse for drink." "I am far from saying," says the writer, "that every nurse under the old system was drunken or dissolute, but I do say that, as a rule, their moral character was unsatisfactory, and that the long hours of work, with no regular interval allowed during the daytime for proper air and exercise, together with the practice of eating their food in the impure air of the wards, render the supporters of the old system largely responsible for the low moral, as well as physical, condition of the nurses who work under it."

2. That the night nurses slept whenever they could, "regardless of the wants and dangers of their patients, of whose pillows and blankets they often made free use for their own convenience and comfort, and helped themselves from the patients' private store of food, and, whenever it was practicable, from the patients' allowance of wine and spirits as well." (What, it will be asked, is the advantage of the free press of these enlightened times if such scandals could go on uncontrolled!). Further, that they did their own "washing," during the hours of the night, and converted the ward into a drying ground; and that for the duty of night nursing "very aged and feeble, to say nothing of hopelessly drunken, women were considered fit."

3. That both day and night nurses were under the control of a "woman called the 'sister,'" who was little more than an experienced housekeeper, who, among other duties, "kept and gave out the wine and spirits ordered by the doctor, and either partook of them or not herself as she felt disposed." "It was unusual for a 'sister' to be moved from one ward to another, and therefore, in course of time, if she were at all an intelligent woman, in spite of a want of general education and a total absence of any special training in the work of her calling, she would become expert in various ways, especially in attendance upon the medical staff, and in prompt and skilful obedience to their orders. *She would learn to watch critical cases in the doctor's absence, and to act with ability under his orders.* [The italics are our own.] After some years at her work it would be strange indeed had she not accumulated a certain amount of experience in the treatment of various diseases of the particular kind she may have had to deal with in her own ward. But all this time she must have remained in absolute ignorance of the first principles of nursing the sick, for she had never seen nursing practised, much less had she been taught to nurse herself."

4. That the doctors go so far as to say that "if the nurses were drunken and dissolute it was of no consequence," &c.; that doctors are not necessarily able to tell good nursing from bad, and that because they want the sisters in the wards when they make their visit they object to their getting air and exercise.

5. That doctors object to the new system, because they fear that public attention may be drawn "to practices and experiments which are better not mentioned beyond the walls of a hospital." That they dislike the moral restraint which the presence of the modern "sister" imposes upon them, and they object to be obliged to "consider either their own manners or the feelings of the nurses." "The presence of refined intelligent women in the wards imposes a kind of moral restraint upon the words and ways of both doctors and students, which some of them desire to get rid of, and I have no hesitation in saying that it is against this, as much as anything else, that they are now at Guy's Hospital resisting with all the might they possess. Yet this unconscious restraint might in time prove powerful to smooth down the roughnesses of medical students, who are, as a class, universally acknowledged to be uncouth."

6. That the presence of the medical staff in the wards is often "a hindrance of a serious kind to the nurse's work;" that students dare to go behind screens without asking the permission of the officiating nurse, and regard nurses as machines for answering questions and clearing up "any mess they may choose to make." That "familiarity" existed between house doctors and nurses, and that this "contributed largely to the low tone of morality for which the wards were remarkable."

This is the indictment which Miss Margaret Lonsdale brings against the physicians, surgeons, students, sisters, and nurses of Guy's Hospital. In every class of persons there will be a certain number who are ignorant and vicious, but we cannot think that the public will regard Miss Lonsdale's article as anything more than an angry tirade, which is not meant to be taken literally. It is easy to gather up hearsay and bits of scandal and to write as if faults were the rule and not the exception; but such a course is not wise, is not charitable, and it will be repudiated by many of the followers of Florence Nightingale.

Digitized by Google

Miss Lonsdale is a clever writer, but she is impetuous and lacks judicial spirit. The article demands no serious answer from us. We only hope that the treasurer and governors of Guy's Hospital will, one and all, read it carefully, and that they will then appreciate the dangers of the sentimental course upon which they have entered.

THE ANNUAL "CHANGE."

THE season, so far as it is governed by the Session of Parliament, will probably be late this year; if, indeed, it be possible to enter upon serious business after the commotion and delay which have occurred. It may not be a regretful consequence of this state of things if the effect should be to postpone the annual "change," to which most persons are already looking forward, to a little later in the year than custom determines. Of course, the time of movement for the multitude of sportsmen and their families will be governed by the festival of St. Grouse, which occupies a fixed place in the calendar; and as this particular saint is much worshipped by those who owe their first allegiance to St. Stephen, the session of Parliament—however important or urgent its responsibilities may be—must be arranged to suit the grouse. The postponement is not, therefore, likely to be for long. If it has the effect of enabling the ordinary class of Londoners to enjoy their "outing" some six or eight weeks later than usual, the experience is not unlikely to be both pleasing and satisfactory. We manage our holidays badly in England; some go too early, before the long dragging trail of the winter has been obliterated by summer suns; others contrive, or are compelled, to go away in September and October, when London is most enjoyable. A considerable proportion of the ordinary population of the metropolitan district have no notion how bright and cheery the parks, and even the streets of the great city, are during the months in which fashion has ordained that the upper and the upper middle classes shall desert the capital. Later on, in November, when the wandering great return to their homes, they find ample cause for complaint as to the climate of London, and regret their inability to remain out of it. Could the holiday season be so arranged that we left London in October or November for, say, six weeks, and took a second holiday of the same length in the spring, we should succeed in making the best of life by living in the best places at the best times. The effect on both health and spirits would be beneficial, because it would sometimes happen that we saw other great cities—for example, Paris and the Continental capitals—when their ordinary inhabitants were at home! As it is, we are wont to find the normal elements of social life absent in our travels abroad. The conditions of climate are not so equable over these isles and the adjacent Continent, that it is impossible to arrange the interchange of visits, so that the multitude of "change" and health seekers may be advantaged in respect both to society and sun.

ENTERIC FEVER IN SHEFFIELD.

THE prevalence of enteric fever in Sheffield has during the past few months assumed epidemic proportions. During last year it appears from the returns of the Registrar-General that 91 deaths were referred to fever, principally enteric, within the borough, of which 36 were registered in the fourth quarter. In the first thirteen weeks of this year, ending 3rd inst., no less than 64 deaths from fever were recorded, and six other fatal cases were returned last week; these figures imply, on the assumption that the proportional mortality of the disease has not exceeded the average, that since the beginning of the year there have been more than 700 cases of enteric fever within the borough. The fatality of fever in England continues to decline both steadily and rapidly, and during the last quarter its annual death-rate in twenty of the largest English towns averaged only 0·25 per 1000; in the several towns it ranged from 0·04 and 0·05 in Brighton and Wolverhampton, to 0·40 and 0·84 in Liverpool and Sheffield. Thus the death-rate from fever in Sheffield last quarter was more than twice as great as that which prevailed in Liverpool, the town with the next highest rate. The annual rate of mortality from all causes in Sheffield has for some time been remarkably low, and averaged but 21·6 in the first quarter of this year, against 25·5, the average rate in the twenty towns. It may be presumed, therefore, that the recent excessive number of fever deaths in Sheffield is due to a specific outbreak, the causes of which we trust will be carefully investigated. We may take this opportunity to note that so far as we know no annual report on the sanitary condition of Sheffield has been published since the late Dr. Griffith's report for 1877. This is subject for regret, since the Sheffield reports published by the late medical officer were valuable contributions to urban vital statistics. Sheffield is the only large English town from which we have been unable to obtain a health report for 1878. We trust that Dr. Hime intends to publish a bi-annual report for 1878 and 1879, in order that there may be no break in the series of statistical reports for the borough.

SALE OF POISONS.

ONCE more the attention of the public has been directed to the notorious abuse of the Sale of Poisons Act; this time by Mr. Henry Hubbard, vice-president of St. Mary's Hospital. Having recently been called to a case of death from an "overdose of chloral taken through misadventure," he practically tested the facility with which this and allied drugs are obtained, by sending round one of his youngest children to various chemists and grocers, and found no difficulty in thus obtaining from them, without any restriction or question whatever, those poisonous drugs. The reason for the facility lies in the fact, repeatedly pointed out in these columns, that certain special preparations of chloral, &c., are protected by the Government stamp as patent medicines. Mr. Hubbard has done good service in again drawing attention to the anomalies of our law—which allows the protection of a patent to materials which are poisonous in any guise,—to the advantage it may be of the public purse, but to the great danger of individual members of the community.

DIPHTHERIA AND TYPHUS IN RUSSIA.

FROM the 27th January to the 13th March, 269 villages were reported infected with diphtheria in the Government of Poltava. The population of these villages amounted to 451,937, and during the period referred to there were 908 new cases of diphtheria, of which 520 were fatal. Diphtheria is still seriously prevalent in Voronege and its suburbs. The hospitals are said to be encumbered with patients. The disease has broken out in the government of Yénisseisk. The larger number of the villages are infected, and there is great want of medical aid and of hospitals. From the 6th to the 13th March there were 730 deaths recorded in St. Petersburg (475 males and 255 females). Typhus caused 22 per cent. of the mortality. The deaths reported from maculated typhus were 64 in number.

In a sitting of the Medical Society on the 26th March, Professor Andreïeosky read a report on hygiene, and particularly on the hygiene of schools. He spoke highly of the hygienic regulation of English schools, described this as "une véritable perfection," and as the envy of other nations of Europe!

At Kharkov a special course of training, of three weeks'

Digitized by Google

duration, has been organised for sisters of charity. Three detachments of sisters have undergone this course already, and a first detachment, ten in number, after an examination, has been despatched to give assistance in localities where diphtheria is prevalent. A second detachment, consisting of twenty-eight sisters, will presently follow. A third is being prepared for examination. The course of instruction is for the most part practical, and given in the hospitals. During the progress the sisters receive four lessons in anatomy and physiology, three in pharmacy, three specially relating to diphtheria, and eighteen in hygiene and disinfection. If the sister passes a successful examination she receives a certificate stating her fitness to join a sanitary detachment.

BROWN-SEQUARD ON THE TRANSFER OF SENSIBILITY.

AN interesting communication was made to the Académie des Sciences at its last meeting by Dr. Brown-Séquard, on the substitution of hyperæsthesia by a lesion of the nerve centre, for anæsthesia produced by a previous lesion. In animals of three species—dogs, guinea-pigs, and rabbits—especially in the latter, he first divided one-half of the pons Varolii immediately behind the middle cerebellar peduncle. The effect of this lesion varied, even as regards sensibility. Frequently, however, especially in rabbits, the same effect was produced as by a hemisection of the spinal cord—more or less considerable hyperæsthesia on the side of the lesion, and more or less marked diminution (sometimes complete loss) of sensibility on the opposite side. Each change was most marked in the hind limbs. He then divided the opposite half of the spinal cord at the level of the sixth dorsal vertebra, and quickly found that after this second lesion the corresponding hind limb, which had lost sensibility after the cerebral lesion, was not only sensitive but hyperæsthetic, while the other limb, hyperæsthetic after the lesion of the pons, became anæsthetic after the second lesion. The hyperæsthesia in the limb on the side of the spinal lesion was as marked as in an animal in which the same section had been made without any previous lesion of the pons.

In another series of experiments, after having divided the right lateral half of the brain at the level of the anterior extremity of the cerebral peduncle, and having found a more or less considerable diminution (and sometimes complete loss) of sensibility in the limbs of the opposite (left) side, he divided the left half of the medulla in two rabbits, and of the spinal cord in six others. He then found hyperæsthesia in the left hind leg, which had previously been anæsthetic, and anæsthesia in the right hind leg, which had been hyperæsthetic. Here, as in the first set of experiments, the second lesion not only removed the effect of the first, but substituted the opposite condition.

If the results of these experiments are compared with the remarkable effects, in which anæsthesia in man, even due to organic disease of the brain, has been cured by the application of galvanic currents, and the interesting observation of the transfer of anæsthesia and hyperæsthesia, published by Charcot, Dumontpallier, Debove, and others, Dr. Brown-Séquard believes that we must reject the notion that the anæsthesia produced by an encephalic lesion necessarily depends on the alteration or destruction either of perceptive centres or of conductors transmitting the sensory impression to these centres. The results of these experiments can, he adds, be readily explained by the views he has previously advanced. Certain parts of the cerebro-spinal centre possess a remarkable power to abolish the functions of other parts of the centre by an "inhibitory" influence. The same parts, or others, possess also another power, hitherto unstudied, by which an irritative lesion may augment the function of other parts more or less distant, by an influence which he terms "dynamogenic." The experimental facts, for instance, may be explained by regarding the anæsthesia as the result of an inhibitory influence exerted upon the sensory elements of the spinal cord, and the hyperæsthesia as the effect of a dynamogenic influence upon the same elements. Other conclusions which he believes follow are—(1) That we have no right to infer from the appearance of anæsthesia, after an encephalic lesion, that the conducting tracts or sensory centres are injured. (2) That in spite of his early observations, which seemed to prove a decussation of the sensory part in the spinal cord, this theory must be discarded. (3) That one-half of the pons suffices to conduct the sensation from both sides of the body.

HEALTH IN SCHOOLS.

WE are anxious that it should be understood by those managers of schools who have already favoured us, or are now sending communications with particulars of the structural and domestic arrangements of their establishments, the dietary supplied to their pupils, the hours allotted to study, recreation, and sleep, together with other matters of interest—that the information supplied will be deemed confidential in so far as the writers may desire that it should be so treated. Our object will be to draw general inferences and cull suggestions from the data supplied; and if it appears expedient, we may ask for such further statements as seem necessary to make our summary of the facts complete. It will greatly help the undertaking if school-keepers and teachers will send their replies at their early convenience. We are prepared to receive communications from schools where boarders are taken from the number of six upwards; and shall be especially glad to be informed on all points relating to the mental and physical discipline of the pupils.

MEASLES FATALITY IN PLYMOUTH.

THE epidemic of measles which has prevailed in Plymouth since the beginning of November last shows no sign of abatement. During the last seven weeks of 1879, 44 fatal cases were recorded within the borough, and in the thirteen weeks ending the 3rd inst., 136 additional cases were registered. Plymouth suffered from severe epidemics of measles in 1871, 1874, 1876, and in 1878, but the epidemic now prevailing is considerably more fatal than any in recent years. During the ten years 1870–9 the annual death-rate from measles in Plymouth averaged 0·71 per 1000 of the estimated population, whereas the average rate in the twenty towns did not exceed 0·51. With reference to this exceptional fatality of measles in Plymouth, it cannot be without interest to consider the evidence which the general mortality statistics of the borough afford of its sanitary condition. During the ten years under notice the average annual death-rate in the borough was equal to 22·2 per 1000, and rose from 22·0 in the first, to 22·4 in the second half of that period. Thus the Plymouth mortality in the last quinquenniad exceeded by 2 per cent. that which prevailed in the preceding five years. This fact becomes the more unsatisfactory when we consider the steady decline which has recently taken place in the mortality of our largest towns. In the twenty large English towns dealt with in the Registrar-General's weekly return, the average mortality during the past five years was lower by 4·7 per cent. than that which prevailed in the preceding quinquenniad. Indeed, if we exclude London, where the decline of mortality has been very slight, the decrease in the nineteen provincial towns was equal to 9·5 per cent. The increased mortality in Plymouth side by side with the large decline in most other towns, deserves the serious consideration of the urban

Digitized by Google

sanitary authority and of the ratepayers of Plymouth. It may be well to notice another fact which affords evidence of retrogression in the health of Plymouth. Infant mortality, which in the nineteen provincial towns was more than 12 per cent. lower in the last than in the previous five years, showed a decline of but one per cent. in Plymouth. The proportion of deaths under one year, to births registered in Plymouth was equal to 161 per 1000 during the five years 1870—4, while it was 160 in the following five years ending 1879. The extent to which it is possible to control zymotic fatality in urban populations is one of the most important and interesting of sanitary questions, and the unsatisfactory character of recent mortality statistics in Plymouth suggests an intimate connexion between the constantly-recurring measles epidemics in that town and acknowledged defects in its sanitary condition.

THE LATE DR. HEATON.

THE following minute of the Council of the Leeds School of Medicine has been forwarded to us for publication:—"The Council desires to record its deep sense of the great loss it has sustained in the death of Dr. J. D. Heaton, whose valuable services were devoted to the Leeds School of Medicine with untiring zeal for a period of thirty-six years. Dr. Heaton lectured successively upon Botany, Materia Medica, and the Practice of Medicine; and three times occupied the presidential chair. For the last fifteen years he fulfilled the onerous duties of treasurer to the school, in which capacity his mature judgment and watchful supervision conduced very materially to the success of the school. The Council further beg to tender to Mrs. Heaton and her family their deepest sympathy with them in their recent bereavement."

SCHOOLS AND INFECTIOUS DISEASE.

A DIFFICULTY in the way of enforcing the absence from school of children attacked with infectious disease has arisen from the fact that such absence deprives the little sufferers of the prospect of rewards for regular attendance. This difficulty has been met, so far as regards Liverpool, by the energy of Dr. Taylor, the medical officer of health, through whom the question has been brought under the notice of the Liverpool Council of Education. Dr. Taylor has received a letter from Mr. Hance, clerk of the School Board, giving extracts from a communication from the Council, to the effect that such enforced absences would not in future be counted against the children in computing their claim for premiums.

DIABETIC HYPERMETROPIA.

THE ocular complications of diabetes are well-known, and diabetic cataract, retinal hæmorrhages, optic neuritis, and paralysis both of the intrinsic and external muscles of the eye are often met with. Dr. Landolt contributes an article to *El Siglo Medico*, of Madrid, and calls attention to a symptom which has hitherto attracted but little attention. A woman, aged sixty-one, consulted him with reference to her sight. Long vision had always been good, and she had also seen well at a short distance with the aid of glasses, which, however, had now become inefficient. Upon examination he found that she had a hypermetropia of 1·25 dioptrics (= old No. 30), visual acuity 0·5, presbyopia 5 dioptrics (old 8). With these glasses she saw well, so that the change of the sight depended upon a change in the refraction, rather than upon an alteration of the visual acuity. This change had occurred after a fall six months before, and in consequence of which she had suffered from pains in the back and hips, as well as from glycosuria. At the time of consultation there were 229·4 grammes of sugar in 2630 cubic centimetres of urine analysed. The specific gravity was 1040. Fifteeen days later the hypermetropia was only 0·75 dioptrics (old 50), and after four months 0·25 (old 156). At the end of five months it had entirely disappeared. The patient had become emmetropic, as before, and had returned to her old glasses. Coincidently with this increase of the refraction the quantity of sugar in the urine diminished, and when the hypermetropia had become 0·75 dioptrics it had disappeared altogether. The author attributes this diminution of refraction (hypermetropia) to the infiltration of sugar into the vitreous humour, in consequence of which the index of refraction is increased, whilst the general refraction of the eye is lessened.

RUSSIAN HOSPITALS.

AT a recent meeting of the Society of Public Hygiene, St. Petersburg, Dr. Andrievsky raised the question of the reorganisation of Russian hospitals, and the adoption of a new method of dealing with the patients sent to them. It appears that the hospitals too frequently contain incurable cases, which might equally well be treated at home, to the serious limitation of the accommodation for cases of acute sickness. He suggests the organisation of a system which would admit of the incurable securing medical care at their own houses. To the objection that many of these cases consist of very poor persons who have sought refuge in the hospitals from their misery, he replies to the effect that the function of the hospital is the relief of sickness and not of pauperism, and that the latter should be otherwise provided for.

A considerable amount of overcrowding is reported in the hospitals of St. Petersburg, owing to the increased demands upon them from the prevalence of infectious diseases in the capital, notably typhus. It is stated, moreover, that from the central hospital bureau, at which persons have to apply for admission, being situated in one of the hospitals, opportunities occur for the dissemination of infectious diseases which should be avoided, and the establishment of an office detached from any hospital is advocated.

HOME FOR FEMALE INEBRIATES.

LORD SHAFTESBURY appeals on behalf of the St. James's Home for Female Inebriates, and the appeal is made in the powerful form of which his lordship is a master when great sins or evils have to be dealt with. The reclamation of habitually drunken women is certainly a very difficult matter, and especially so when the initiatory steps can be taken only with their consent and concurrence. But Lord Shaftesbury tells us that the most apparently incorrigible inebriates have submitted of their own accord to the rigorous, though kind, discipline of this home, and, further, that they are fully aware of the benefits they receive. This is important testimony. But it will need to be made more specific, and much multiplied, to convince us that the law, in its present weak form, will be of much use. We shall be glad to be supplied with evidence on this subject.

FARR TESTIMONIAL FUND.

A MEETING of the executive committee, charged with the raising of a testimonial in honour of Dr. William Farr, C.B., F.R.S., took place on Thursday afternoon. Now that the general election is over, an appeal will be made to the profession, the learned societies, and the public in general, in furtherance of the object in view. A first subscription list will shortly be published.

THE SICK CHILDREN'S HOSPITAL.

THE twenty-eighth anniversary of the Hospital for Sick Children, Great Ormond-street, was held on the 8th inst., at Willis's Rooms, Sir James Paget in the chair. The number of in-patients last year was 1114, of out-patients

Digitized by Google

12,300. The Convalescent Home in connexion with the institution has received 3302 children during the past ten years. Sir James Paget's appeal on behalf of this excellent charity was characterised by his usual eloquence, and, fortified by remarks from Lord Aberdare, Viscount Gort, Sir R. Wilbraham, the Bishop of Rangoon, Dr. Dickinson, and Dr. Ord, was responded to by the announcement of subscriptions amounting to nearly £2000.

HOWELL v. WEST AND JONES.

THE trial of the action brought by Dr. Howell nominally against the head master and the medical attendant of the Royal Medical Benevolent College at Epsom, for breach of contract in respect to the care and treatment of his son, who recently died of scarlet fever at the school of this institution, not having been concluded at the moment of our going to press, we are compelled to leave over a summary of the evidence, and to reserve comment until next week.

THE LATE DR. SHARPEY, F.R.S.

WE regret to announce the death of Dr. William Sharpey, F.R.S., the well-known Emeritus Professor of Physiology in University College, London. Dr. Sharpey had been residing at Hastings for some months on account of bronchitis, and returned to London about a fortnight ago. He took cold at the beginning of last week, and died, after a few days' illness, on Sunday last, the 11th inst., in his seventy-ninth year. On Thursday afternoon the corpse was taken to University College, where it was met by a large number of distinguished persons, and thence to Euston Station to be conveyed to Arbroath for interment. The *cortége* included about fifty private carriages. We hope to publish a sketch of his long and useful life in our next issue.

A REPORT prevailed in Dublin last week that some uncertainty existed in reference to the validity of Dr. Lyons' election for that city, on the ground that when elected he held an appointment under Government. Dr. Lyons is physician to the Richmond Hospital, for which he receives a salary from the Parliamentary Grant. There seems to be some misapprehension as to the law on this point. Servants of the Crown, with certain exceptions, may sit in Parliament; but the act of accepting an office after election voids the seat. When, therefore, a candidate holds his appointment *before* return to Parliament his election is not affected by it. When a member of Parliament accepts an office under the Crown he is disqualified, but may seek re-election and sit on a new return, as is the practice with members of the Government.

A TABLET in memory of Surgeon-Major Shepherd, who was killed at Isandula, has recently been placed in the Church of Leochel-Cushnie. The tablet, which was prepared by Messrs. Macdonald, Field and Co., Aberdeen, is of oblong shape, and is exceedingly tasteful in design. It bears in neat lettering the following inscription:—"In memory of Peter Shepherd, M.B., University of Aberdeen, Surgeon-Major, Her Majesty's Army, born at Craigmill, in this parish, on 25th August, 1841, who sacrificed his own life at the battle of Isandhlwane, Zululand, on the 22nd January, 1879, in the endeavour to save the life of a wounded comrade. Erected by his friends and brother officers."

AT a recent meeting of the board of guardians of St. George's, Hanover-square, a letter was read from the Commissioners in Lunacy in reference to the want of asylum accommodation for lunatics in the county of Middlesex. In the event of the county asylums and licensed houses being reported as full, the Commissioners fear that accommodation will scarcely be found nearer than the Northampton County Asylum. They agree with the guardians of St. George's Union in thinking that many cases exist in all three asylums for Middlesex of old demented people and others who would be properly taken care of in well-regulated workhouse infirmaries. The discharge of such patients is a matter which would probably be best secured by regular visits of a committee of guardians of every union to the asylums. They should take with them their own medical officer (16 and 17 Vic., cap. 97, sec. 65), and confer with the medical superintendent as to the suitability of particular cases for treatment out of an asylum.

THE Board of Trade inquiry into the formation of banks at Barking and Crossness, alleged to be caused by the outfalls of sewage, and to be obstructive to navigation, has now terminated, having occupied twenty-five days. Sir Charles Hartley sat as umpire, and Mr. F. J. Bramwell and Captain Galton as arbitrators, the latter for the Thames Conservancy Board, and the former on behalf of the Metropolitan Board of Works. After hearing the reply of Mr. Pope, Q.C., on behalf of the Thames Conservancy Board, the umpire said he and the arbitrators would, after having carefully weighed all the evidence, report, if possible jointly, to the Board of Trade.

AT a meeting of the Board of Guardians of St. Albans, attention was called to the excessive mortality among infants during the past year in the sanitary district, as shown by the report of Dr. Saunders, medical officer of health. At Tring the death-rate of infants under one year of age was reported to be 140 per 1000. The matter was referred to Dr. Saunders for further report.

DR. TIDY, analyst for Essex, whilst reporting favourably of the food sold in the county as regards its genuineness, echoes an objection made by other analysts as to the method of purchasing samples. He thinks more satisfactory results would be obtained if private individuals exhibited a greater interest in the efforts made to put a stop to food adulteration.

WE understand Mr. Lister, F.R.S., has consented to preside at the annual distribution of prizes at the Bristol Medical School, on Monday, May 3rd, at 4 P.M. On that day he will also give a demonstration at the Royal Infirmary; and on Tuesday, May 4th, another at the Bristol General Hospital, at twelve o'clock.

THE twenty-seventh report of the Charity Commissioners for England and Wales contains some very strong observations by the Commissioners, deprecating investments on mortgage by charity trustees, and advocating the placing of funds affected by a charitable trust in Government securities.

MR. JOHN BRIGHT, M.P., has been nominated as the next Liberal Lord Rector of Glasgow University, and the right hon. gentleman has intimated his acceptance of the nomination. The term of office of Mr. Gladstone, the present Lord Rector, will expire in November next.

WE learn from the Russian journals that H. E. Count Orlof-Davydow, who is a graduate of the University of Edinburgh, having appeared for the purpose before the British ambassador, acting as a justice of the peace, has recorded his vote in favour of Professor Lyon Playfair.

THE post of Honorary Surgeon to Her Majesty the Queen in India, vacant by the death of Surgeon-General Arnott, C.B., has been conferred upon Surgeon-General Hunter, M.D., Bombay Medical Department.

Digitized by Google

SIR WILLIAM JENNER, Bart., will take the chair at the twentieth festival dinner of the Royal Medical Benevolent College, to be held at the Langham Hotel on the 28th inst.

DR. W. B. CARPENTER, the representative of the University of London in Firth College, Sheffield, has resigned his position owing to ill-health.

SURGEON-MAJOR J. M. CUNNINGHAM has been appointed Surgeon-General in medical command in India, in succession to Dr. Beatson.

THE district medical officer has reported an increase in the number of cases of whooping-cough at the Norwood parish schools.

MR. G. PIZEY, M.R.C.S., of Clevedon, has, says the *Bristol Mercury*, been stricken with paralysis.

A MEDICO-SANITARY PILGRIMAGE TO MECCA.

THE veil which has hitherto shrouded the sacred city of Mahommedanism from the familiar knowledge of the unfaithful is being withdrawn, and that in a manner and after a fashion which was unlooked for. The function of adventurous travellers, such as Burckhardt, Burton, and Maltzan, so far as it concerns the central spot of the Mahommedan world, will presently be at an end, and we have promise of becoming early acquainted with the innermost recesses of the sacred city, habits of life of its population, and proceedings of the pilgrimage, from the pens of Mahommedan writers themselves. It is no new thing that the faithful should commit to paper an account of their pilgrimage, as in the instances of the Nawab Sikander Begum of Bhopal, and Hafiz Ahmed Hassan, but their descriptions have been looked upon by the unfaithful rather as literary curiosities than as helpful to that knowledge of Mecca and its sister city in holiness, Medina, which the Christian of the "special correspondent" epoch craves for. But a different sort of author has now entered the field of letters, the English-speaking Mahommedan, cultivated in Western medicine, and capable of judging of the events of the pilgrimage, and of the place to which it is directed, in other than their religious aspects. How this has come to pass is not the least interesting part of the story.

When, in 1865, cholera, radiating from Mecca, spread for the first time in the history of that disease by way of the Red Sea into the basin of the Mediterranean and into Europe, the governing Powers of the Continent discovered that under the altered and altering relations of the traffic with the East by way of Egypt, and its increasing acceleration, the pilgrimage had become a great danger to the Continent, and the holy land of the Hejaz a sort of half-way house for cholera in its migrations by the sea route from India. An International Sanitary Conference held at Constantinople in 1866 formulated certain notions as to this newly-ascertained danger, and each subsequent pilgrimage to Mecca has been carefully watched by the Powers on the Mediterranean littoral in view of cholera or plague, and elaborate measures have been instituted by the Ottoman and Egyptian Governments, the governments most immediately concerned, for the sanitary regulation (much needed) of the pilgrimage, and the arrest (if practicable) of any threatened extension of disease by the returning pilgrims from the sacred cities and the Hejaz. Every year since 1865 a medical Commission has been despatched from Constantinople to the Hejaz to regulate and amend the sanitary conditions under which the rites of the pilgrimage have to be performed there, and generally to give such medical assistance as may be needed by the pilgrims. An Egyptian medical man is attached to this Commission, and its proceedings appear to be reported at the close of each pilgrimage to both the Ottoman and Egyptian Governments, but the report is not made public. The Mahommedan population of India under British rule contributes a large proportion of the pilgrims who each year make the pilgrimage, and we learn from Captain Burton, and more recently from his wife, Mrs. Isabel Burton,[1] that India is one of the chief contributors of impoverished pilgrims to the pilgrimage. India, moreover, as the "home of cholera," is looked to as the prime source of danger from that disease; and although she led the way in endeavouring to subject the pilgrims and the pilgrimage, so far as this fell within her power, to sanitary regulation, she is not regarded either by the Ottoman or the Egyptian Governments, nor generally it may be said by the Governments of the Continent, as represented at the Constantinople Conference of 1866, as having done all she might have done to diminish the chances of the spread of cholera from her shores in the track of pilgrims bound for Mecca. There would appear to have been a sort of simmering discontent with India in this matter since 1866, and at length the Government of India has taken the course of despatching a medical commissioner to Mecca, to report upon the sanitary relations of the pilgrimage, more especially as it concerns British Mahommedan subjects.

In the autumn of 1878 Assistant-Surgeon Abdur Ruzzack, a Mahommedan gentleman in the Indian Medical Service, was directed to visit Mecca, and to study the whole circumstances of the pilgrimage—at the starting-point from an Indian seaport, on the voyage out and home, during the journey in the Hejaz, the stay in Mecca and Medina, and during also the rites of the pilgrimage. This he did; and in the course of last year he reported fully on the subject, adding to his report a series of detailed recommendations for the better regulation of the pilgrimage as affecting British Indian Mahommedan subjects. The report, written in excellent English, is admirable from the acute and comprehensive observation it displays. It presents us for the first time with an adequate account of the sanitary circumstances under which the pilgrimage is performed and the sanitary condition of the sacred cities of the Hejaz; and, apart from this, it is of considerable value for its description of the rites of the pilgrimage. There would appear, from the report, to be no doubt that the Government of India is really not so careful as she might be of our Mahommedan fellow-subjects in pilgrimage, and that she has been less heedful of the fears of the Ottoman and Egyptian Governments and other Powers of the Mediterranean littoral than was to be desired. Abdur Ruzzack shows that she has left numerous things undone, for the better regulation of the pilgrimage, which she might be reasonably asked to do; and he effectually does away with the objection that further interference with it is undesirable, lest such interference should arouse religious prejudice.

Abdur Ruzzack arranges his recommendations, first, (*a*) with reference to the pilgrim previous to embarkation, and (*b*) after his embarkation, and during the voyage: and next, (*a*) with reference to the arrival at Jeddah and the journey to Mecca; (*b*) with reference to the stay at Mecca, and the journey during the rites to Arafat and Mina; and (*c*) with reference to the journey to Medina and back. On each of these subjects he has much to say, but we may not do more than touch upon a few salient points. He proposes that the pilgrim should not be permitted to embark until he has been examined as to his health by a health officer, and until he has given evidence of possessing sufficient means at command to meet the costs of the pilgrimage. It is difficult to over-rate the importance of these recommendations. The first would remove the objection strongly urged by the Conference of 1866 regarding the omission by the Indian authorities to give heed to the state of health of pilgrims before embarkation—an omission which was held to neglect the one safeguard needed to prevent the embarkation of persons in an early stage of cholera. The second recommendation would put a stop to persons entering upon the pilgrimage who were simply religious mendicants, and who form one of the great difficulties in regulating the sanitary conditions of the pilgrims in the Hejaz.

Abdur Ruzzack further recommends the establishment of a complete system of agencies and registration by which the course of the pilgrim could be regulated from the time of his embarkation in India to the time of his landing on his return home, and by which he could be protected from the frauds of self-constituted agents both before embarkation in India and during his stay in the Hejaz. A system of this kind

[1] Arabia, Egypt, India, 1879.

Digitized by Google

appears to be in force among the Javanese pilgrims, and is said to work exceedingly well.

Notwithstanding what has been done for the regulation of the pilgrim-traffic from Indian seaports, much more, it appears, remains to be done in regard to the overcrowding of the pilgrim-ships; and Abdur Ruzzack shows fully what is further required in this respect.

Among the most important of his recommendations in this connexion, are those relating to the medical supervision of the pilgrimage. He would have a Mahommedan medical officer attached to each pilgrim-ship (forbidding pilgrim-traffic in ships of small tonnage); would establish a hospital at Jeddah during the pilgrimage, and attach to it a Mahommedan medical officer, who might also act as pilgrim-agent and assistant to the British Consul, and when the pilgrims move to Mecca would take medical charge of them there, leaving a substitute at Jeddah. The Mahommedan medical officers of the different ships, as they arrive, would be placed in charge of caravans bound for Mecca and Medina, and they would act as a medical staff under the agent during the rites of pilgrimage. There can be no question whatever of the necessity for this recommendation being acted upon, and of its feasibility; and we apprehend that in regard to the question of expense, the whole Mahommedan population of India would be glad to co-operate with the Government of India in promoting a scheme which is so completely in accord, as it would appear, with their religious teachings, and which is so obviously to be desired in the interest of their co-religionists.

That this remarkable report will exercise an important influence upon the action of the Government of India in this matter can scarcely be doubted; and we trust to learn that its author has or will shortly receive some special mark of honour for the mode in which he has performed a difficult and delicate duty.

HEALTH OF LARGE ENGLISH TOWNS.

FOURTEENTH WEEK OF 1880.

URBAN mortality showed a marked decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population in England and Wales, 6021 births and 3239 deaths were registered last week. The births exceeded by no less than 836, while the deaths were 36 below, the average weekly numbers during 1879. The deaths showed a decline of 339 from the number returned in the previous week, and were equal to an annual rate of 22·5 per 1000, against 21·9 and 24·9 in the two preceding weeks. During last quarter the death-rate in these towns averaged 25·5 per 1000, against 24·2, 25·2, and 27·5 in the corresponding periods of the three years 1877–8–9. The lowest death-rates in the twenty towns last week were 16·9 in Leicester, 17·2 in Leeds, 17·5 in Portsmouth, and 18·5 in Brighton. The rates in the other towns ranged upwards to 26·2 in Oldham, 28·6 in Manchester, 28·6 in Norwich, and again the highest rate, 31·3, in the borough of Plymouth. The excessive rate in Plymouth continues to be mainly due to the exceptional fatality of measles.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 424 and 531 in the two previous weeks, were 449 last week. They included 143 from whooping-cough, 112 from measles, 89 from scarlet fever, and 41 from fever, principally enteric. The annual death-rate from these seven diseases averaged 3·1 per 1000 in the twenty towns, and ranged from 0·7 and 1·0 in Wolverhampton and Brighton, to 6·3 in Oldham, 7·2 in Nottingham, and 13·2 in Plymouth. The largest proportional fatality of measles occurred in Plymouth, Nottingham, Hull, and Oldham; of scarlet fever in Salford; and of whooping-cough in Manchester. The 16 deaths from diphtheria in the twenty towns included 11 in London and 2 in Birmingham. Six more deaths were referred to fever in Sheffield, against 4 in each of the three previous weeks. Small-pox caused 15 more deaths in London and its suburban districts; but no death from this disease was recorded in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 167 and 172 in the two preceding weeks, further rose to 177 on Saturday last; 42 new cases of small-pox were admitted to these hospitals during last week, against 31 and 47 on the two previous weeks. The Highgate Small-pox Hospital contained 18 patients on Saturday last.

The fatality of lung diseases showed a considerable decline in our urban population last week. The deaths referred to diseases of the respiratory organs in London, which had been 315, 334, and 395 in the three preceding weeks, declined again to 365 last week, and were 91 below the corrected weekly average; 219 resulted from bronchitis, and 103 from pneumonia. The annual death-rate from diseases of this class was equal to 5·2 per 1000 in London last week; in Liverpool the rate from the same diseases was 6·0 per 1000.

FEES AT THE COLLEGE OF SURGEONS.

FOR some time past, as we have more than once announced, a Committee of the Council of the Royal College of Surgeons has been considering the best means of giving effect to the principle adopted by the Council about a year ago of requiring candidates who have been rejected at any examination of the College, to pay, on re-examination, such fees as will cover the expenses of the re-examination. The Committee presented its report at a meeting of the Council held on the 11th ultimo, and at a meeting held on the 8th inst. the adoption of the report was confirmed. It may, however, be well to state that the proposed changes cannot be put into force until the Secretary of State has sanctioned the necessary alterations in and additions to the bye-laws. The following are the regulations relating to the payments by candidates from the membership and fellowship.

"For the Primary Membership Examination the fee shall be five guineas, or, if it be the re-examination of a previously unsuccessful candidate, three guineas; and the fee shall not be returned to a candidate who fails to pass the examination or re-examination. For the Final Examination or re-examination the fee shall be fifteen guineas, over and above all charge for stamps; and ten guineas shall be returned to a candidate who fails to pass the examination or re-examination.

"The fees to be paid for admission to the Fellowship by examination, over and above all charge for stamps, shall be as follows:—(*a*) for members of the College, if succeeding on their first examinations, fifteen guineas; but with liability to higher payment (as hereinafter provided) in cases where re-examination is required; (*b*) for persons not members of the College, thirty guineas.

"Of the above respective amounts, one-third part shall be paid before admission to the Primary (or anatomical and physiological) Examination; and the remaining two-thirds, together with the charge for stamps, shall be paid before admission to the Final Examination.

"Of the fee of five guineas to be paid by members of the College before they are admitted to the Primary Examination, no portion will be returned to unsuccessful candidates; but of the fee of ten guineas to be paid by persons who are not members, half will, in case of rejection, be returned. Of the fee of ten guineas to be paid by members of the College before they are admitted to the Final Examination, no portion will be returned to unsuccessful candidates; but of the fee of twenty guineas to be paid by persons who are not members, half will, in case of rejection, be returned. And in all cases any money which has been prepaid as a charge for stamps will be returned to rejected candidates.

"Candidates who, having failed at an examination, subsequently desire re-examination, are, on each such occasion, subject to the same conditions regarding payment as those on which they were first examined: except that in all cases previous payments shall be taken into account, and that, if in any case a total payment of thirty guineas for the Fellowship has been made, no further payment shall be required."

ST. JOHN AMBULANCE ASSOCIATION.—On the 8th inst., at the Mission Hall, Princess-street, Wapping, Mr. John Furley, of the Order of St. John of Jerusalem in England, presented certificates to the pupils who had, out of the class recently closed in the district, satisfied the surgeon examiner (Dr. H. Crookshank) of their capability of rendering first aid to injured persons.

Correspondence.

"Audi alteram partem."

ON A NEW METHOD OF EXCISING THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—The somewhat unsatisfactory result which, in a considerable proportion of cases, follows excision of the knee, as regards the position of the limb and its firmness as a support, especially in those instances where the patient is not kept sufficiently long under observation, has suggested to me the desirability of some modification in the mode of operation now commonly employed.

In some cases there is, from the first, a tendency for the tibia to become displaced backwards upon the femur, whereby the area of apposition of the two bones is lessened, and consequent diminution in the strength of the union is produced, as well as unnecessary unsightliness of the limb. In other cases bending of the limb occurs after a certain amount of consolidation has taken place, and consequent weakness, deformity, and shortening are produced, as well as an inequality of strain—a portion only, instead of the whole, of the divided area bearing the pressure of the body-weight, and hence the part upon which the undue proportion of pressure comes is more likely to become the seat of a fresh outbreak of the disease.

To remedy these defects I would suggest trial of the following operation, which has not, so far as I am able to learn, been yet employed. I have not yet had an opportunity of seeing its results, but the operation itself I have found presents no particular difficulty upon the dead subject, and would, I believe, be still more easy upon the living, where the ligaments have been relaxed and more or less destroyed by pulpy infiltration.

A transverse incision, as in the ordinary operation, should be made across the knee just below the apex of the patella, but should be carried only through the skin and subcutaneous structures. The joint should then be opened at the sides, leaving the ligamentum patellæ intact. The capsule of the joint and the interarticular ligaments or their remains having been divided, the thigh should be flexed upon the abdomen to relax the rectus muscle, and the leg being either extended upon the thigh or flexed to such extent as to allow of easy manipulation, the saw should be introduced between the ligamentum patellæ and the tibia at such distance above the tubercle of the tibia as the disease may require, the section being made from before backwards. The slice of tibia having been removed, the necessary amount of the femur should next be sawn off in a similar manner; to facilitate this it is well to partially divide the aponeurosis attached to the sides of the patella, in a direction parallel to the long axis of the limb. The patella may then be readily turned round, so that its articular surface is exposed, and this should be removed by a horizontal section exactly in the same way as it is in Gritte's amputation. The next step consists in removing with chisel or saw a small portion of the anterior surfaces of the tibia and femur to which the refreshed surface of the patella should be adjusted, and the rest of the operation concluded in the ordinary way. In order to keep the bony surfaces in apposition, an apparatus made on the plan of a small Lister's or a Signoroni's tourniquet may be applied, the one pad resting on the splint at the back of the limb, and the other pressing lightly but firmly upon the patella; this, of course, would be put on after the dressings are in place.

By this means a continuous, as it were, anterior splint of bone and tendon is preserved on the front of the limb, and the patella by its union with both bones forms a bony arch across the fissure left between the tibia and femur; at the same time the tendency of the hamstring muscles to draw the tibia backwards is counteracted by the preservation of the extensor tendon.

Even supposing that no bony union were to take place between the patella and the other two bones, still, the presence of the bone and tendon would add greatly to the strength of the limb. Further, the quadriceps would still be enabled to act in bringing forward the limb in walking; also the appearance of the limb would be improved by the presence of the patella, by avoidance of the atrophy of the muscles on the front of the thigh resulting from their disuse as a consequence of the division of their tendon.

The most useful saw for the operation will, I think, be found to be a Butcher's saw, the blade of which should be passed beneath the ligamentum patellæ, or quadriceps tendon, as the case may be, and then adjusted in the bow; or in default of this a narrow Spence's saw with movable back may be employed.

No difficulty will, I think, be found in removing all diseased tissue that may be necessary, and although the operation takes somewhat longer time in its performance, it seems probable that it would give improved results.

I remain, Sir, yours, &c.,

G. A. WRIGHT, F.R.C.S.

Royal Infirmary, Manchester, March, 1880.

A MEANS OF DIAGNOSIS OF RENAL CALCULUS.

To the Editor of THE LANCET.

SIR,—At the conclusion of the recent debate upon my paper on "Nephrectomy," at the Royal Medical and Chirurgical Society, I had intended to draw attention to a method of diagnosing calculus in the kidney, which had rendered me the greatest service in a case treated since the writing of the paper. Having, however, omitted to do so then, I venture to think that recording the matter here may be of use to others in dealing with a class of cases beset with difficulties in their earlier stages as to diagnosis, and with dangers later on. The following brief notes of a case will illustrate the point sufficiently.

At the beginning of February my colleague, Dr. John Williams, very kindly transferred to my care at University College Hospital a woman whom he believed to be suffering from some renal tumour, a view which I also adopted on hearing the history, and on manual examination. But the question as to the nature of the tumour presented many difficulties. The symptoms had only developed comparatively recently—i.e., some three or four months before; the morbid mass was not very large, was movable and nodulated; it was painful on handling, and felt to be particularly hard. There was pus in the urine, but never any blood. To be brief, the diagnosis appeared to lie between: (1) a new growth of the kidney; (2) tubercular infiltration of the renal tissue; (3) a calculus in the organ. In the hope of distinguishing between these three conditions I adopted the following measures on Feb. 21st:—

The patient was put under chloroform to admit of more thorough examination of the tumour. This showed it more than ever to be renal. I then took a long, slender aspirator needle, carefully cleansed, and forced it into the loin at a point midway between the crest of the ilium and last rib, directing the point towards the abdominal aspect of the spinal column, and a little upwards. At the same time the tumour was pressed backwards towards the needle by the hand on the abdomen. The vacuum (previously made) having been turned on, the needle was thrust steadily on into the tumour, and, at about two inches from the skin surface, came upon a calculus. The point could be almost heard grating on the stone, and the grating could, it was believed, be felt by the hand on the tumour in front. Only about two drachms of thick, yellow, and odourless pus came away in the aspirator. The diagnosis was thus rendered certain. But had the tumour been a new growth or tuberculous, I had hopes that enough débris would have come away in the instrument to enable us to judge of its nature, as in the case of growths in other situations.

The withdrawal of even this small quantity of pus seemed to benefit the patient. The pain was relieved, the temperature fell, and she felt better for the next few days. No blood was noticed in the urine afterwards.

In view of the rapid wasting, loss of strength, and suffering, and the hopelessness of the case if left to itself, I proposed to cut down and remove the kidney. The patient, however, declined any operation, and returned home a few days later. That removal of the organ in this case, before abscesses had formed around it, and the patient was altogether exhausted by the disease, would have been the proper treatment I am still satisfied. It would, I believe, have been less dangerous than simple removal of the calculus by

Digitized by Google

incision into the kidney through the loin, with all its later risks.

The point indicated for puncture will always find the lower end of the kidney as verified by dissection beforehand. It appears strange that this almost obvious method of diagnosing stone in the kidney early should not have been employed before this, though aspiration of hydro- and pyonephrosis and peri-renal abscess is common. But though so simple, there appear to be no records, so far as I have found in a rather extensive examination of the subject, that it has been made use of.

I am, Sir, yours obediently,

ARTHUR E. BARKER, F.R.C.S.I.,
Assist.-Surgeon and Assist.-Professor of Clinical Surgery, at University College Hospital.

Welbeck-street, W.

CHRONIC MENINGITIS WITH OSSEOUS DEVELOPMENT IN THE DURA MATER.

To the Editor of THE LANCET.

SIR,—The following case, from the length of its duration, and several other particulars, seems to me worthy of publication.

On Dec. 29th last, at about 2 P.M., I was sent for to see the body of a man (H. W——, aged forty-nine) who was last seen alive at about 10 A.M., and was found dead in his room two hours afterwards. As the consequence of this I subsequently made a post-mortem examination, and, never having seen him alive, I shall give the particulars of that examination first.

There was nothing to note externally, excepting the appearance of an old fracture of his nasal bones. The space between the brain and its membranes was occupied with a considerable amount of serum; the left lateral ventricle contained about one ounce and a half, and the right about half an ounce, of clear fluid; there was no effusion of blood in any part of the brain; the arachnoid was thickened and opaque, and inseparable from the pia mater in places, chiefly in the median line over the longitudinal fissure: lying deep in the latter, attached to, and embraced on either side by, the falx cerebri, was a small plate of bone, about one inch in length and a quarter of an inch in breadth, convex on its upper, straight and dentated on its lower margin; there was no irritation or lesion of any kind visible in its immediate neighbourhood. I could find no traces of disease in any of his thoracic or abdominal organs, the kidneys in particular being quite healthy. And now for his previous history, which I have subsequently learnt.

From ten years of age he had been subject to epilepsy. The attacks recurred for the first few years at intervals of from one to two months, until during the last six years he had them every fortnight or every week, and at last twice a week, the longest interval that he ever enjoyed being, for one period only, three years. He appears never to have done any work, and to have been quite well between the attacks until the last five or six years. During this latter period he had symptoms of cerebral irritation, especially for a day or two before the fit would come on, even threatening to kill those around him. He never had any form of paralysis other than a certain want of control over his bladder. He was always somewhat drowsy, sullen, and irritable. There is an entire absence of any history of epilepsy or cerebral disease in the family.

I am, Sir, yours truly,

Tunbridge Wells. W. M. SATCHELL.

ALGIERS AS A HEALTH RESORT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of the 20th ult. I read a letter of my friend, Dr. Lockhart Robertson, in which he comments very severely upon the unwholesome sanitary conditions of the town of Algiers, and compares it very unfavourably in that respect with the towns upon the Riviera. I would be the last to pretend that the sanitary arrangements in Algiers were anything like perfect, for, more especially from the great drought which has existed for the last two years, also from the imperfect system of water-closets in general use by the French both here and in France, bad smells are only too common here as elsewhere on the Continent. Still, I cannot help thinking that Dr. Robertson has exaggerated his description. During this winter about 1000 English visitors have passed a longer or shorter time in the hotels here of which he complains so much, not one of whom has suffered from typhoid fever, a result at the present time, when that disease seems rife both at home and abroad, which can compare very favourably with the returns from other places of health resort; nor have I ever seen any cases of illness in these hotels the cause of which could be directly attributed to the effects of sewer gases. The few cases of typhoid fever which have occurred here this winter, to which Dr. Robertson refers, have almost without exception been confined to the suburbs of Mustapha Supérieur; of these five came under my care, and in two of them there was distinct evidence of the fact that the patients had been attacked by the disease before their arrival in Algiers.

I have had considerable experience in the unpleasant degrees of smells of nearly all the different marine health-resorts upon the shores of the Mediterranean, and I can most unhesitatingly award the palm for intensity to some of the most celebrated ones upon the opposite side, which it might be invidious to name. Trusting that you may find space in your journal for this,

I remain, Sir, yours, &c.,

Algiers, April 2nd, 1880. W. THOMSON, M.D.

THE CROTON-OIL TREATMENT OF RINGWORM.

To the Editor of THE LANCET.

SIR,—May I be allowed a word in reply to Mr. Smith's letter in reference to the croton-oil treatment of ringworm, in THE LANCET of last week, as he appears to have misunderstood a sentence in my paper on this subject in THE LANCET of March 27th.

I did not say that kerion is a subcutaneous abscess, but that the production of either kerion or subcutaneous abscesses is unnecessary.

A pustule will clear of ringworm only an area as large as comes under the influence of the inflammatory process. A rash of scattered pustules may fail to free of ringworm the affected part, if spaces beyond the sphere of their action exist between the pustules. I have often seen diseased hairs reappear in such interpustular spaces. It is necessary, therefore, that the pustules be in close propinquity and deeply seated.

In my experience a close-set pustular rash, involving the tissues to the depth of the hair-follicles, produces all the good effects of a more far-spreading and severe inflammation. Some inflammatory infiltration accompanies such a rash, and the hairs are loosened.

As regards the principle of treatment, the all-important point, Mr. Smith seems to agree with me. I did not for one moment suppose that Mr. Smith was aware that I had previously brought the matter before the profession.

I am, Sir, your obedient servant,

WYNDHAM COTTLE, M.B. Oxon., F.R.C.S.,
Assistant Surgeon to the Hospital for Diseases of the Skin, Blackfriars.

Savile-row, W., April 10th, 1880.

DISLOCATION OF THE ASTRAGALUS (SIMPLE).

To the Editor of THE LANCET.

SIR,—Cases of this nature are so rare and often so little amenable to treatment that it is worth while to record one that had a favourable termination.

A young man, aged nineteen, tall and active, when engaged in athletic sports, in taking a leap, got his foot fixed in the ground and fell forwards. Dr. Carter, who was near at hand, saw him immediately, and, finding that there was dislocation of the astragalus, attempted, with other assistance, to reduce it by direct extension, but without success. When I saw him about an hour afterwards I found the foot presenting an appearance of truly formidable distortion. The toes were turned outwards. The distal head of the astragalus formed a marked prominence on the inner aspect of the foot, with the integuments tightly stretched over it. Immediately beneath the inner malleolus was a deep depression corresponding to the normal situation of the displaced bone. The heel was drawn back, and the tendo

Digitized by Google

Achillis tightly strained. On the outside the external malleolus projected in a very marked manner, the skin being here also tightly strained over it. The dislocated bone was quite immovable.

Chloroform having been administered, a round towel with a clove-hitch at one end was passed over the heel and across the instep. To the other end pulleys were attached, and counter-extension made over the pelvis. After a few minutes' extension the bone slipped into place with an audible click, and with the effect of at once removing all the distortion which had previously been so marked.

The after-treatment was of the simplest kind, and the patient rapidly recovered with a useful and undamaged limb.

In the process of reduction I had the benefit of the co-operation of Mr. Stockwell, Dr. Carter, and Mr. Scott, our house-surgeon.

I need scarcely say the result was highly satisfactory, as the distortion was extreme, and the prospect of replacing the bone apparently very problematical.

I am, Sir, your obedient servant,

Bath, March, 1880. R. T. GORE.

TRICHINOSIS v. ENTERIC FEVER.

To the Editor of THE LANCET.

SIR,—Having read your article, "Trichinosis *v.* Enteric Fever," I would suggest that the temperature charts of the best-marked cases of trichinosis should be published, as these might afford a valuable guide to the differential diagnosis of these diseases in the future.

I am, Sir, yours, &c.,

PYREXIA.

EDINBURGH.

(From our own Correspondent.)

IN hospital Dr. John Duncan has had two cases of lateral lithotomy. One of these, performed in the Glasgow method with the rectangular staff, presented some difficulty, for the extreme narrowness of the pelvic outlet and the large size of the stone hindered extraction. The patient is doing well.

Dr. Keith's series of successful consecutive ovariotomies—over eighty in number—has been interrupted by a death. This occurred in a case where operation had been performed as a last resort, at the earnest solicitation of the patient's relatives. In the wards in the Royal Infirmary there have been two interesting operations of late—one for removal of a large fibro-cystic tumour over forty pounds in weight, and another where a large single cyst with many adhesions burst during the operation. It is to be hoped the managers may attend to the further illumination of the great theatre, so that Dr. Keith may again give pleasure and instruction by operating publicly. It is also a matter of doubt whether there is any advantage derived from the use of the two clinical theatres as operating rooms. Formerly in the old Infirmary a student might see various surgeons at work after one another in the same arena; he might enter at the commencement and leave at the conclusion of any operation he felt a special interest in; now, however, in the new building he is perplexed sometimes by seeing three operations advertised. Each of these is carried on in a separate theatre, but all takes place at the same time. He cannot conveniently see them all, as he might have done had old customs been adhered to; he must take his choice of one, and one only. The system may be more convenient for the surgeon; it does not seem to be better for the student, and is apt to lead to the establishment, as it were, of three or more small schools, under one common roof, each following its own leader.

A third house physician will be appointed to the University clinical wards, and the junior house surgeon will become resident after the month of October.

Following the example of the University, the resident physicians attached to the extra-mural medical wards will, in future, be selected by competitive examination.

THE salaries of the district medical officers of St. Pancras have been increased as follows:—Dr. Thomas Sayer's, from £100 to £140 per annum; Dr. Walter Smith's, from £100 to £130; and that of Mr. Sydney L. Smith, from £130 to £140.

Obituary.

ALFRED LEGGATT, F.R.C.S. ENG.

BY the death of Mr. Leggatt the profession and society have alike lost a practitioner of no common order. The profession has lost a member who sustained its dignity, upheld its honour, and exemplified its best characteristics with singular fidelity and success; and society, in its highest walks, has lost a trusted, able, and conscientious medical adviser, whose death has left a void scarcely likely, in some instances, to be adequately filled.

For over thirty years Mr. Leggatt enjoyed a practice in the most aristocratic quarter of the metropolis such as seldom falls to the lot of any man; and he retained it as only a man of ability and high character could do. His practice was extensive and lucrative, being almost exclusively among the upper classes. He enjoyed the confidence of Cabinet Ministers of both parties, and was the trusted medical adviser of some of the most distinguished personages in the State.

Of singularly fine presence and gentle manners, he had also the charm of honest purpose; for the uprightness of his mind shone through all his acts. Of him may be said that which can be truthfully said of very few, that he lived what he professed—a Christian life. Such as his belief was, he faithfully strove to live up to it; and it can truly be said of him that his life was one of unobtrusive and gentle piety.

Mr. Leggatt's practice, like that of the majority of general practitioners, was chiefly medical and obstetrical, with very little surgery. For such work a medical qualification would have appeared the most appropriate leading licence, but, like so many others who are never called upon to practise surgery after acquiring their licence, he only held the M.R.C.S., and after that the L.S.A. A few years ago, however, the honorary F.R.C.S. Eng. was conferred upon him; and no one more truly merited a distinction than he whose blameless life had brought honour to his calling.

Mr. Leggatt was a good, but kindly, judge of men; and it may be mentioned in illustration that two of his old assistants who lived with him when quite young men, are now Fellows of the Royal College of Physicians of London and teachers in Metropolitan Schools of Medicine — viz., Dr. B. Yeo of King's College and Dr. Wiltshire of St. Mary's. Mr. Leggatt leaves a widow and large family to mourn his loss. He died at the age of sixty-five, after a laborious and successful life.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at Meetings of the Board of Examiners on the 8th, 9th, 12th, 13th, and 14th inst.:—

Edward D. Thring, William H. Horrocks, Charles R. Elgood, Ernest Hudson, William C. Wilkinson, William R. Buckell, Frederick J. Bollen, and Francis F. Culhane, University College; George Frost, John B. Sutton, Hugh R. Neblett, John F. McMillan, Edgar R. Dimsey, William E. Ransom, M. W. Russell, Walter E. Wynter, Alan E. Tate, J. H. Douty, William Hern, Charles G. Brodie, and Sidney R. Dyer, Middlesex Hospital; Frederick L. Nicholls, William C. Beatley, William Tibbles, James Donald, John L. Rodwell, David L. Jones, James K. Lewis, and Samuel Wyborn, Charing-cross Hospital; William A. W. Smith, Percy Pope, Arthur F. G. Codd, Percy Edgelow, and George Y. Eales, St. George's Hospital; Henry F. Illewiez, Robert F. Fox, Michael Angelo, Robert Black, Oliver W. Sharood, John H. Thomas, John Sinclair, George Adkins, John C. Davies, Frederick H. Kenny, William Coates, Walter F. Dale, Ralph Holyoake, R. Buksh, and John W. Davis, London Hospital; Thomas D. Pryce, James Berry, Edward J. Jenkins, R. J. Collyns, D'Arcy Power, and Alfred J. Anderson, St. Bartholomew's Hospital; Harry L. R. Dent, Robert G. Lynam, Hugh R. Beevor, James J. C. Dounet, John W. G. Kealy, Sidney Ellis, and Walter T. Brooks, King's College; John H. H. Williams, Louis A. Dunn, Charles H. L. Meyer, and John H. Booth, Guy's Hospital; Oliver F. N. Treadwell, Arthur Goulston, Walter Hull, and David W. H. Llewellyn, St. Thomas's Hospital; John R. Cater, St. Mary's Hospital; Joseph Pollard, Cambridge and King's College; Edward A. G. Doyle, Westminister Hospital; S. T. Pruen, Francis J. Walker, Harold Hendley, and H. E. Bateman, St. Bartholomew's Hospital; Frederick Knight, Edward Skipper, Edward W. Von Tunzelmann, and Frederick H. Lane, University College; G. D. Porter and Bertram H. L. Stivens, King's College; Henry Green and Alfred H. Willoughby, St. Mary's Hospital; Robert Sanderson and Gilbert E. Butler, Westminister Hospital;

Digitized by Google

Llewellyn A. Morgan, St. Thomas's Hospital; William B. C. Treasure, Charing-cross Hospital; Charles Reuner, Würzburg and University College; and William J. Sheppard, St. Thomas Hospital and Newcastle-on-Tyne College of Medicine.

Of the 173 Candidates examined during the last and present week twenty-six failed to satisfy the Board of Examiners and were referred for three, and one Candidate for six months' further Anatomical and Physiological Study. The Primary and Pass Examination for the Fellowship of the College will take place on the 21st and 27th of May, respectively.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 8th:—

Kánga, Jamshedji Kharshedji, Bombay.
Pickering, Robert Whitworth, Park-road, Reyton.
Usher, John Edward, Melbourne, Australia.

The following gentlemen on the same day passed the Primary Professional Examination:—

Thomas Wm. Buckley, St. Thomas's Hospital; William Cecil Penwick, Guy's Hospital.

COLLEGE OF PHYSICIANS IN IRELAND.—At the April examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Matilda Charlotte Chaplin Ayrton, Charles James Barry, Joseph Bradley, John Joseph Daly, James Davison, John Knox Denham, Anthony Kidd, Chas. George Drummond Masse, Cornelius O'Brien, John Pollock, William James Swanson.

MIDWIFERY.—Matilda Charlotte Chaplin Ayrton, James Davison, Anthony Kidd, Edward Erskine Moore, Cornelius O'Brien, Oliver William Spromlle, William James Swanson.

On the 7th inst. the undermentioned were admitted to the Fellowship of the College:—

Isaac Ashe. | Christopher Joynt.

On the 12th March:—

Robert A. Hudson.

UNIVERSITY OF OXFORD, April 15th.—The degree of Doctor of Medicine was conferred on E. Jacobs, Corpus.

THE Hospital Saturday collections in Sheffield on the 10th inst. realised £747.

A BUST in bronze of J. Marion Sims, M.D., LL.D., has been presented to the Alumni Association by the surgical staff of the Jefferson College Hospital.

MR. G. ADAMS, the medical officer of the Nailsea district of the Bedminster Union, has been awarded a gratuity of £20, in recognition of extra services rendered by him during the fever epidemic in his district.

MERCER'S HOSPITAL, DUBLIN.—Some alterations, including a new operation theatre and accommodation for extern patients, are contemplated, and plans have been selected for those and other purposes, which it is estimated will cost over £4000. About £1500 has already been received or promised, and the governors trust that further aid will be obtained, so as to allow them to commence the work without delay. During the past year the receipts amounted to £2247, and the total expenditure to £3182, or a balance on the wrong side of £935.

BEQUESTS ETC. TO MEDICAL CHARITIES.—The Hospital for Sick Children, Great Ormond-street, received nearly £1900 in donations on its twenty-eighth anniversary last week. The Right Hon. Sir William Erle, P.C., formerly Chief Justice of the Court of Common Pleas, bequeathed £500 to the Royal Hants County Hospital at Winchester, £300 to the West Sussex, East Hants, and Chichester General Infirmary and Dispensary, and £300 to the London Fever Hospital. The Cumberland Infirmary, Carlisle, has received £100, less duty, under the will of Miss Thurnam. The North Eastern Hospital for Children, Hackney-road, has received £200, less duty, under the will of Mr. Samuel Yates, and £100 anonymously, per Mr. J. Lister Godlee. Mr. Johnston Jonas Foster, of Moor Park, Ludlow, bequeathed £250 each to the Bradford Infirmary and Dispensary, the Bradford Eye and Ear Hospital, the Bradford Fever Hospital, and the Halifax Infirmary. General Philip Spencer Stanhope, colonel of the 13th Regt., bequeathed £100 to the St. Marylebone General Dispensary. The Drapers' Company have given an additional fifty guineas to the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor. The Rev. G. B. Paley bequeathed £50 to the Cottage Hospital, Millenhall. The Rev. J. Heyworth bequeathed £600 to the Bristol Royal Infirmary.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

ADAMS, J. D., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Yeovil Rural Sanitary District.

ADOLPHUS, T. F. P., M.R.C.S.E., has been appointed Assistant Medical Officer at the Camberwell Infirmary and Workhouse, for three months, on probation.

BURMAN, C. C., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Western District of Belford Union; also Medical Officer to the Workhouse, vice *J. Millar*, M.D., resigned.

BUTTERS, J. G., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Whitchurch and South Lydford District of the Tavistock Union.

COYLE, Mr. D., has been appointed Analyst for the Southern Division of the County of Derby.

CROSSBY, J. P., L.R.C.P., L.F.P.S.G., has been appointed Medical Officer of the Sunderland Union Workhouse, at a salary of £200, with private practice.

FISHER, Mr., has been appointed Resident Accoucheur at the London Hospital, vice Davies, resigned.

FOTHERGILL, Mr. E., L.D.S., has been appointed Dental Surgeon to the Newcastle-upon-Tyne Infirmary.

HENDERSON, G., M.B., C.M., has been appointed one of the Medical Officer of the Coldstream and Eccles Dispensary, vice Brown, deceased.

MCCUAIG, D., M.D., L.R.C.S.Ed., has been appointed Consulting Physician to the North Riding Infirmary, Middlesbrough-on-Tees.

MCGACHEN, F. W. D., L.F.P.S.G., L.M., has been appointed Medical Officer of the Hanslope District of the Newport Pagnell Union.

NORTHEY, G. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Milton Abbot District of the Tavistock Union.

ORTON, J., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Foleshill District and the Workhouse of the Foleshill Union.

PATTERSON, T., M.D., C.M., has been appointed Medical Officer for the Fourth District of the Oldham Union.

SMYTH, J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Senior House-Surgeon to the Belfast Royal Hospital.

VOLCKMAN, Mr., has been appointed House-Physician at the London Hospital.

WOLFENDEN, Mr., M.B., has been appointed House-Physician at the London Hospital.

WRIGHT, W. H., M.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer for the Normanton District of the Shardlow Union.

Births, Marriages, and Deaths.

BIRTHS.

BULL.—On the 7th inst., at St. Oswald's House, Stony Stratford, the wife of William H. Bull, L.R.C.P.L., M.R.C.S.E., of a son.

LUCEY.—On the 14th inst., at Southampton, Hants, the wife of William C. Lucey, M.D., of a son.

MOSS.—On the 9th inst., at Chardville, Elphinstone-road, Southsea, the wife of Edward L. Moss, M.D., Staff-Surgeon H.M.S. *Atalanta*, of a son.

REID.—On the 11th inst., at Belgrave Villas, Stratford, E., the wife of Walter Reid, Staff-Surgeon H.M.S. *Wivern*, of a son.

MARRIAGES.

FERNELL—PORTER.—On the 13th inst., at St. Mark's Church, Sheffield, by the Rev. T. Woollen Smith, M.A., Vicar of Calvertown, Notts, Henry George Tudor Fernell, M.A. Cantab., Solicitor, to Edith, elder daughter of the late John Taylor Porter, F.R.C.S., of Sheffield.

SANKEY—CARR.—On the 8th inst., at St. Oswald's Church, Shipton Oliffe, Gloucestershire, by the Rev. Douglas Powell Ware, B.A., Curate of St. Mary's Episcopal Church, Glasgow, assisted by the Rev. W. H. Stanton, M.A., R.D., J.P., Rector of Hasleton, Gloucestershire, W. Arthur C. O. Sankey, third son of W. H. O. Sankey, M.D., of Sandywell-park, Gloucestershire, to Annie B. Fox, eldest daughter of the Rev. John A. Carr, B.A., Rector of Shipton Oliffe, W. Shipton Sollars.

WILSON—STYRING.—On the 8th inst., at All Saints' Paddock, Huddersfield, by the Rev. Wm. Gordon, M.A., Vicar, assisted by the Rev. Canon Calvert, M.A., Vicar of Huddersfield, David Wilson, M.B., to Emma, eldest daughter of Thomas Styring, Esq.

DEATHS.

BIRCHENALL.—On the 22nd ult., at Park-street, Macclesfield, John Birchenall, M.R.C.S.E., L.S.A.L., aged 81.

BIRNIE.—On the 6th inst., at Don-street, Old Aberdeen, Sarah Augusta, widow of M. Birnie, Surgeon, of Aberdeen, aged 85.

JAGOE.—On the 5th inst., at the Royal Victoria Hospital, Netley, E. R. Jagoe, A.B., Surgeon, A.M.D.

MCCREA.—On the 2nd inst., at Templepatrick, co. Antrim (the result of an accident), Samuel McCrea, M.D.

MAITLAND.—On the 9th inst., at Devonshire-terrace, Elizabeth White, widow of John Maitland, M.D., Indian Medical Service, and second daughter of the late Lieutenant-Colonel Hobbs, Royal Engineers.

POTTLE.—On the 9th inst., at Bunhill-row, E.C., Edgar George Pottle, M.R.C.S.E., L.R.C.P., aged 40.

SHARPEY.—On the 13th inst., at Torrington-square, London, William Sharpey, M.D., LL.D., F.R.S., formerly Professor of Anatomy and Physiology in University College, aged 78.

N.B.—*A Fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE USE OF THE FORCEPS.

DR. P. C. WILLIAMS, in a paper read before the Baltimore Academy of Medicine, and published in the *Maryland Medical Journal*, discusses in a full and able manner the subject of the use of the forceps in midwifery. In labours "tedious," not so much from the time occupied in the process as from the pain and exhaustion induced, he would use the forceps, taking care that the rigidity of the parts is first overcome. Also in cases of malposition or unusual size of the child, and in deformed pelvis, he would, as a rule, prefer the instrument to version, because resort to the latter expedient leads to the danger of prolapsed cord, with its accessory perils, and likewise exposes the mother to unnecessary risks. Dr. Williams concludes with a caution, which he thinks it wise to observe in every case where the forceps are applied at the "superior strait"—viz., "always insert the hand, or at least the extremities of the fingers, into the os uteri before you introduce the blades of the instrument. This affords an infallible guide, and is a great protection to the mother."

F.R.C.S.—There were four vacancies last July for election into the Council of the College of Surgeons. The unsuccessful candidates were Messrs. T. Bryant and R. Barwell; the former polled 97 votes, including 9 plumpers; and the latter 22, including 8 plumpers.

Dr. Buchanan, (Glasgow.)—The late arrival of the proof rendered it impossible to insert the addition. The request shall be complied with.

TREATMENT OF GONORRHŒAL OPHTHALMIA.

To the Editor of THE LANCET.

SIR,—I walked this day's LANCET in order to see whether Dr. Charles Bell Taylor or anyone besides would challenge Mr. Critchett's claim to be the first to divide the eyelid in cases of gonorrhœal ophthalmia. In a communication which you published in THE LANCET, April, 1876, p. 360, Dr. Taylor concludes thus: "While on the subject of gonorrhœal ophthalmia, I may mention that I have found the greatest benefit, in some of these cases, from the very free division of the external canthus; this enables the surgeon to expose the eyeball, turn the lids inside out, incise chemosed conjunctivæ, and freely apply such local remedies as may be indicated. Spasm is also relieved, and the free bleeding occasioned is most beneficial."

Had Mr. Critchett consulted the "Medical Digest," section 1834-6, he would not have written: "I determined to adopt a somewhat heroic and novel proceeding, and one that has not, I believe, been published," and then describes division of the eyelid in the middle line, instead of at the external canthus, the latter plan being, I should fancy, preferable.

Yours obediently,

RICHD. NEALE, M.D. Lond.

Boundary-road, South Hampstead, April 9th, 1880.

BROMIDE OF ETHYL.

THIS drug, which seems to be obtaining some reputation, especially in America, where its use has been warmly advocated by Dr. Levis, forms the subject of an article in the New York *Medical Record* of the present month, by Dr. Marion Sims, who describes a case in which the hydrobromic ether was employed for the performance of Battey's operation. During the first twenty minutes about two ounces of the ether had been used; the patient then vomited, and again twenty minutes later, with severe straining. On three occasions during the operation there was considerable opisthotonos, with rigidity and twitchings of the extremities; her pulse, however, was strong and full. In all, four and a half or five ounces of the anæsthetic was used in the course of the operative proceedings, which lasted an hour and a half. The patient suffered from distressing retching and vomiting, with diarrhœa and headache, and died some twenty-one hours afterwards in severe convulsions. Dr. Sims inclines to the opinion that in this case death was caused, at least indirectly, by the ether, and utters a caution against its use in prolonged operations, and where there is kidney disease.

Inquirens.—Nothing can be done in the study without practice.

SMALL-POX HOSPITALS.

To the Editor of THE LANCET.

SIR,—Your issue of March 20th, containing an article on Dr. Bridges's Report to the Local Government Board on Small-pox Hospitals, has only just reached me. In that article you have clearly pointed out the possible fallacies of some of Dr. Bridges's conclusions and methods of reasoning, more especially in that part of his report which deals with their influence, for good or for evil, on the immediate neighbourhood surrounding them, as you say it has never been averred that these institutions produce evil results on the large districts or parishes in which they may be situate, but that they do, or that they may, produce evil results on the immediate locality surrounding has been maintained, and with some reason.

Until very recently, and for some years previously, I have resided in the vicinity of one of these institutions, the Fulham Hospital, and I speak with a considerable amount of personal knowledge of the locality surrounding it, and of the extent to which it has been affected by small-pox. Since the opening of the hospital the immediate neighbourhood surrounding it has never been free from the disease, except when the hospital itself has been empty or nearly so of patients. In the autumn of last year (1879) the medical officer of health for the Fulham district gave, in his Annual Report for 1878, a most ghastly description of the ravages of the disease up to that date. On analysing his report, it was found that the scenes there depicted occurred in the streets of his district contiguous to the hospital grounds. Since then the disease has continued, and I have now before me an extract from a local paper, dated March 20th, 1880, in which a report is made to the Fulham Board of Guardians with reference to the disease. It states that from three of the districts of the Fulham Union, during the previous month, 23 cases of small-pox had been removed, 22 of these cases having been sent from one district only, and from that part of the district next to the hospital—in fact, from one street in its immediate neighbourhood. This has been precisely the case with the Brompton district of the Kensington Union. A portion of it adjoins the hospital, and I am well acquainted with it, having been associated with its Poor-law medical officer during the late, or rather present, epidemic, as it still continues. Up to the autumn of 1879, 223 panper cases were removed from the Brompton district to the Fulham Hospital. Of this number, 203 were removed from ten or twelve streets in the immediate neighbourhood of the hospital; the remaining 20 occurred in the more distant parts of the district in a scattered and sporadic form. It may be mentioned that the infected area formed about one-tenth of the area of the whole district, and about one-fiftieth of the whole of the parish of Kensington, in one street. In that side of it exposed directly to the hospital scarcely a house escaped infection. It will not, therefore, appear very surprising that many of the general public, and also many competent professional men, should be unable to believe that the hospital is entirely innocent in the matter. Those whose duty, however, it is to report officially on the subject think otherwise. So far as I have seen of their reports, they appear to make the mistake you refer to, treating the matter as one affecting a whole parish or large district, losing sight of the immediate neighbourhood of the hospital—a manifest fallacy in so far as it has reference to the locality directly surrounding the hospital and its influence thereon.

The reasons generally given for the long continuance of the epidemic are: insufficient vaccination and revaccination, concealment of cases, carelessness of washerwomen, the visitings of servant maids to infected districts and epidemic influence. All these, no doubt, have their action; but they are also equally applicable to those districts where the disease has not existed, or only so in a mild or sporadic form. It would seem as though some other cause or causes should be looked for.

It appears to me that the term epidemic influence as applied to this long-continued outbreak of small-pox—a disease, of all others, spread by contagion and infection—should be received with some modification; at any rate, of all the large towns in the United Kingdom until very recently, London alone has been subjected to it, and that for a period of now over three years.

t the risk of encroaching too much on your space, I would wish to make one remark on the observation of Dr. Bridges with reference to the conveyance of microscopical spores. He says that it is absurd to suppose that they can be conveyed through the atmosphere for an indefinite distance. This is true enough. Distance, however, is a relative term. Manifestly, however, the spores or contagium in the instance of small-pox must be carried some distance. As the majority of cases are infected by some unseen, and therefore distant, source, direct contact is by no means necessary. The question arises, What is the probable distance at which infection ceases? Is it the same in an infected house containing one patient, in an ambulance under the same conditions, as it is in a large hospital containing 150 severe cases of the disease, saturating the surrounding atmosphere with spores, or whatever form the poison may take? Are conditions of atmosphere, locality, elevation, &c., the same in the one case as the other, as regards the power of infecting at a distance? This is a question well worth inquiring into; and, as you say, it is incumbent on some one of the governing authorities to make it, seeing that in spite of the establishment of these hospitals the disease is now entering on its fourth year of scarcely uninterrupted progress in London.

I am, Sir, your obedient servant,

March 29th, 1880. SURGEON-MAJOR.

"NEWSPAPER NOTICES OF MEDICAL WORK."

WE called attention in THE LANCET of November 29th to two newspaper paragraphs in reference to ordinary surgical operations. One of these paragraphs was from the *Sydney Echo*, and described a lithotomy and an amputation by, respectively, Dr. M'Laurin and Dr. Cox. These gentlemen forward us the following letter from the Editor of the *Echo*, which completely exonerates them. We gladly insert the letter, but Drs. M'Laurin and Cox will agree with us that it is no part of a newspaper reporter's duty to describe the ordinary operations of surgery in an infirmary or out of it, and the sooner the practice is discontinued the better.

Echo Office, Sydney, January, 1880.

"DEAR SIR,—I see that a paragraph which appeared in the *Echo* with reference to medical work at the Sydney Infirmary has been copied into THE LANCET, apparently for the purpose of condemning unprofessional efforts to obtain notice through the press. I mark particularly the following sentence: 'We cannot so much blame lay newspapers for inserting such paragraphs as we blame medical men who contribute them for publication.' I regret that an unjust imputation should thus be cast upon you and Dr. Cox. One of the duties of the city reporter of the *Echo* is to visit the infirmary every day, and in the ordinary course of business he obtained the information contained in the paragraph referred to. There is not the slightest colour of truth in the innuendo conveyed in the sentence I have above quoted from THE LANCET. In conclusion, I would say that, in my long experience of newspaper life, I have not known any instance in which a Sydney medical man of recognised standing has attempted to obtain recognition by the press in the unprofessional manner censured by THE LANCET.

Yours very truly,

"Dr. M'Laurin." "SAMUEL COOK.

PUERPERAL CONVULSIONS.

DR. T. A. POPE, of Wilderville, Texas, writing on this subject, says:—"I feel justified in saying that if bloodletting be eschewed, chloroform inhalation as a temporary expedient, chloral and the acetate of potash be given freely, followed by free purgation, and a diuretic mixture when no contra-indication exists, very few patients will be lost from puerperal convulsions."

ENGLISH AND FOREIGN WEIGHTS AND MEASURES.

To the Editor of THE LANCET.

SIR,—Will you allow me to call attention to another victim to the difference between English and foreign weights and measures?

The Italian Consul in Bombay was prescribed an injection of morphia by an Italian doctor; but the chemist mistook *grains* (written "grana" in the prescription) for the French word *grammes!* and, of course, the unfortunate patient died in a very short time. As well as I remember, there are about *fifteen grains* in one *gramme*, so that the extent of the danger of mistaking one for the other can be estimated.

I have recently returned from a long stay in Italy, France, &c., and always found the *greatest difficulty* in making foreign chemists understand the difference; and if I had not known the French language fairly, I should probably have been sacrificed to one of the many English prescriptions I got made up.

I leave the matter in the hands of the medical profession, respectfully suggesting an International Conference to assimilate the weights and measures of all civilised countries.

I remain, Sir, your obedient servant,

April 10th, 1880. NEMO.

P.S.—"Gr." expresses equally *grains* and *grammes*, which is really too *monstrous*, considering the difference between the two!

F.R.C.S., (Manchester.)—At the primary examination for the Membership of the College of Surgeons, which was brought to a close on Wednesday last, 173 candidates had been examined, against 213 in the corresponding period last year, when the rejections amounted to 45 for three months, and 7 for six months.

W. J. H. should at once secure the aid of a skilful general practitioner or surgeon. There are, happily, as yet no special institutions for such diseases.

INFLUENCE OF THE ELECTRIC LIGHT ON VEGETATION.

MR. C.W. SIEMENS has made some further observations on the influence of the electric light on vegetation. In another communication to the Royal Society he detailed a few of the results obtained. He exhibited two pots of strawberries which had been grown in the usual way until the fruit buds appeared, when one of the pots was exposed to continuous light—that is, daylight through the day and electric light during the night, the other being left to the influence of ordinary daylight. The contrast between the two pots, as shown at the meeting, was remarkable: one bore a cluster of large, red, fragrant strawberries; the other a bunch still green, with the exception of one slightly red spot. The ripe fruit was the result of the combined light, from which the conclusion is drawn that electric light may be found useful in the ripening of fruit generally. The ripe strawberries were tasted by the President, and pronounced very good.

A Fellow, (Liverpool.)—There is plenty of time, as the election does not take place until the first Thursday in July, when at least three vacancies will be declared in the Council, caused by the death of Mr Hancock, and the retirement in the prescribed order of Mr. George Busk and Mr. T. B. Curling, both of whom are Fellows of the Royal Society. Sir James Paget, Bart., will take the Chair at the Fellows' festival.

THE PHYSIOLOGY OF THE LARYNX.

To the Editor of THE LANCET.

SIR,—Permit me to reply to Mr. Holmes's letter of December 6th last year. Had I been at home I would have done so earlier.

In my original paper, which appeared in your columns on June 21st, 1879, I not only began by stating it as my firm belief that there is no longitudinal stretching of the vocal cords by muscular action during vocalisation, but concluded that to admit a longitudinal tension by the action of the crico-thyroid muscles was to admit an anomaly in the phenomena of muscular action, in the shape of an increase of the length of a muscle during its contraction. Mr. Holmes in his first letter (June 28th) ventures to admit I am right in reference to this matter, but adds that "the experiments of Müller are sufficient to prove that alterations in the pitch of the voice, at least in the chest notes, are entirely dependent on varied tension of the vocal cords." Mr. Holmes is now "sorry" that I am "able to strain such an absolute agreement" with any of my "theories" out of anything he has written. After remarking that it is not with any theory of mine I have claimed his agreement with me in every letter I have written, but with an argument based upon anatomical and physiological facts, I would ask why Mr. Holmes did not accuse me of straining an agreement after my letter of July 12th, in which I express astonishment that, after agreeing with me so far, he should still have faith in the experiments of Müller. I now learn that the approval is a qualified one. The peculiarity of the particularly intricate and lengthy qualification, however, is that it more than negatives the approval. Mr. Holmes believes in a longitudinal tension of the vocal cords. I most emphatically do not. The process of reasoning by which I try to show why I do not, Mr. Holmes has not as yet ventured to attack. He contents himself with styling it an idea and a theory. I must, therefore, again point out that if I argue correctly that the crico-thyroid muscles do not stretch or make tense the vocal cords in a longitudinal direction, all experiments yet made upon the dead larynx have no value whatever, because they are not faithful imitations of nature; and also that Mr. Holmes is not at liberty to appeal to them for the purpose of qualifying a very positive approval of an argument which avowedly aims at demonstrating their absurdity.

My remarks about the falsetto voice in my last letter sprang from no misconception or want of care in reading Mr. Holmes's letter. I added that "a pure falsetto note has never been emitted by any method of experimentation yet devised," in order to show that if the vocal cords were the all-important structures they are made out to be, some method would have been discovered by this time to get a falsetto note out of them.

In conclusion, I have to invite Mr. Holmes to consider my argument on the action of the laryngeal muscles in THE LANCET of June 21st, 1879.

I am, Sir, yours faithfully,

Kendal, April 7th, 1880. C. R. ILLINGWORTH, M.B.

SUBCUTANEOUS INJECTIONS.

MR. W. J. MARSH, of St. Matthew's Infirmary, Cambridge Heath, offers the following remarks on the above subject:—

None of the preparations at present obtainable are free from objection. The permanent solutions are apt to leak or spill, and the gelatine discs are troublesome, whilst their advantage as regards exact dosage is more apparent than real. What is required are solutions that could be alternately and easily solidified and liquefied. Might not these be obtained by using a certain proportion of gelatine sufficient to enable the solutions to set firmly at ordinary temperatures, but not so much as to prevent them being easily liquefied by heat? A small quantity of salicylic acid or chloral might be added if necessary as a preservative.

An Old Surgeon-Major.—The publication of the General Order regulating the administrative branch of the Indian Civil Service obviates the necessity for the publication of our correspondent's very temperate remonstrance.

A CASE OF DIABETES MELLITUS TREATED WITH SALICYLATE OF SODA.

DR. CHARLES KAUFMANN, of Frankfort-on-the-Main, communicates the following interesting case:—

A lady, aged fifty-eight, consulted me for intense pain she suffered during micturition, and which increased, especially after having passed urine. She had been under the care of another medical man during one year and a half, who told her that her disease was a chronic catarrh of the bladder, and who applied, besides other medicines, injections of chamomile infusion into the bladder, without any amelioration. On examination, I found the mucous membrane of the vagina much excoriated in places, and extremely sensitive. It being evident that the passage of the urine over these excoriations was the cause of the pain, and that the bladder was free from disease, further examination eliciting the well-known symptoms of diabetes, except the hunger; the diagnosis was not difficult, even before the analysis of the urine, which was of a specific gravity of 1038, with five per cent. of sugar. First of all I regulated most carefully the diet, and ordered Carlsbad water to be taken at home, as the patient could not undertake a journey to the spa. The water having been regularly used during a fortnight, the analysis of the urine showed no change at all for the better. I then ordered salicylate of soda in doses of one gramme to be taken three times a day after each meal. After a fortnight the specific gravity had diminished to 1016, and the sugar to two per cent. The medication having been continued for ten days longer, the sugar had quite disappeared, and the specific gravity was 1012.

I. V. R. C.—The minute on the Indian Medical Service by Lord Dalhousie, written in 1856, was subsequently published in this country, and will be found in the Appendix to the Report of Lord Herbert's Commission. It is interesting and valuable; but we do not think it necessary to reprint a portion of it, as suggested by our correspondent.

ARSENIC IN SKIN DISEASES.

To the Editor of THE LANCET.

SIR,—In last week's LANCET you have generously reported an abstract of a paper I read on the above subject before the Medical Society of London. An error has arisen in the report, how I cannot understand, as the abstract as I wrote it is correctly entered on the minutes of the Society. Your report says, "It is sometimes useful to combine it with other drugs, even iron." It ought to read, "It should never be combined with any other drug, not even iron."

I am sorry to trouble you with an explanation on a point that at first sight seems trivial; but the whole object of my paper was to show that, in order to obtain the full therapeutical value of arsenic in diseases of the skin, it should be given alone.

I am, Sir, your obedient servant,

Montagu-square, April 12th, 1880. MALCOLM MORRIS.

A Collector.—The large collection of medical portraits made by Mr. W. Wadd was dispersed; the late Dr. Squibb, Dr. Merriman, the College of Surgeons, and Mr. Stone obtained by purchase most of them. Mr. Squibb's collection is now in the possession of the Royal Medical and Chirurgical Society.

Mr. Harry Dove should address his question to a practitioner; or, if thought desirable, to one of the Professors of Obstetrics, whose names may be easily found in the Medical Directory.

NICTITATION.

To the Editor of THE LANCET.

SIR,—I have three patients, one gentleman and two ladies, all suffering in the same way—viz., a shaking of one eyelid, like a frequent and rapidly repeated wink, and a little occasional twitching at the same side of the face, extending to the angle of the mouth. One lady has good private means, so, having proved my inability to benefit her, I recommended her to consult some physicians of highest repute in London, Dublin, and elsewhere. No advantage has resulted.

Perhaps some kind reader of your valuable journal could recommend, as the result of successful experience, some treatment. He would have my sincere thanks, and my patients shall be duly informed by me of their benefactor.

Yours faithfully,

April 7th, 1880. M.D.

R. V.—Our correspondent will probably have seen ere this the announcement that a mess has been established for the medical officers at Aldershot.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—Will you permit me to correct an error in your report of my remarks at the last meeting of the Pathological Society? I did not say that branched connective-tissue corpuscles occurred in "mucous membrane," but in mucous *tissue*, of which the vitreous humour, the fœtal umbilical cord, myxomata, &c., are examples. I should not have troubled you with this correction were it not that your report represents me to have said not only that which I did not say, but that which is almost certainly erroneous.

I am, Sir, your obedient servant,

Upper Berkeley-street, W., April 9th, 1880. JOHN CAVAFY.

THE

Lumleian Lectures

ON

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.

Delivered before the Royal College of Physicians,

BY WM. ROBERTS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL MEDICINE TO THE OWENS COLLEGE.

LECTURE II.—PART II.

Comparison of the Action of Pepsin and Trypsin.

THE action of pepsin and trypsin, although similar in the main results, is certainly not identical. There is a markedly larger production of leutin and tyrosin in tryptic than in peptic digestion. Moreover, the action of the two ferments on different proteids appears to vary both in character and in energy. Milk is much more readily digested by pancreatic extract than by artificial gastric juice; but in the case of egg-albumen the advantage lies decidedly with the gastric juice. The study of the digestion of egg-albumen by the two methods yielded some interesting results. I employed for this purpose a dilution of egg-albumen with water, in the proportion of one in ten. This remains uncoagulated after being boiled in the water-bath, and furnishes a favourable medium for studying the digestion of albumen—much more favourable than the chopped boiled white of egg usually employed. It permits the ferment to be at once brought into uniform and intimate contact with the particles of the albumen, thus obviating the irregularity and want of constancy which necessarily attends the operation of a solvent acting on solid pieces of variable size, which can only be attacked progressively from their surfaces. In the raw state this solution is digested with extreme slowness by artificial gastric juice, and pancreatic extract is nearly inert on it; but after being boiled it is attacked with energy by both the gastric and the pancreatic ferments. When the boiled solution was treated, in the warm chamber, with pepsin and hydrochloric acid, the transformation of the albumen went on rapidly and without interruption to its close. In the earlier periods of the action the mixture gave a dense precipitate with nitric acid and with ferrocyanide of potassium, but this precipitation became progressively less and less pronounced, until at the end of two or three hours these reagents only produced a slight haze. The albumen was now completely digested, or at least as nearly so as could be reached, for this remnant of a reaction persisted even after a further digestion of twenty-four hours.

When the same solution was treated with pancreatic extract the progress of events was different. For an hour or two (the time varying with the quantity of extract added) there was no apparent change; but at the end of this time the mixture lost its diffluent condition, and became converted into a gelatinous mass, exactly resembling a thin starch jelly. By and by the gelatinous matter broke up into little masses, which floated in a transparent liquid. At this point the action seemed to be arrested. The floating masses of jelly remained almost undiminished in quantity after twenty-four and even forty-eight hours. When the mixture was filtered the liquid portions came through perfectly transparent, and the jelly-like matter was left in the filter. The filtrate was found to be a rich and very pure solution of peptone, uncontaminated with any undigested or half-digested albumen. The jelly-like matter was found to be insoluble in water, hot or cold, but it dissolved readily in acids, and was rapidly digested by pepsin and hydrochloric acid.

If a large amount of pancreatic extract was used, a considerable proportion of the jelly-like matter was slowly dissolved; but the main result was always the same. The pancreatic ferment was only able to convert a part of the albumen into peptone, whereas the gastric ferment converted the entire quantity, with the exception of an insignificant residuum.[1]

In the case of milk, the relation of the two ferments is reversed. Tryptic digestion of milk is rapid, and leaves only a very slight residue; whereas peptic digestion is slow, and leaves a large residue. I have some further observations to make on the digestion of milk by pancreatic extract, but it will be more convenient to take up the subject when I come to speak of the use of this ferment for the preparation of artificially digested food.

Peptogens.

I may here advert to a singular view advanced by Schiff in regard to the production and secretion of pepsin and trypsin. Schiff found that when an insoluble aliment such as white of egg (or fibrin, or meat which had been deprived of its soluble portions) was introduced into the stomach of a fasting animal no pepsin was secreted, and the albumen remained undigested; but if with the albumen certain soluble aliments were introduced into the stomach, then pepsin was produced, and digestion immediately began.

To these substances, which had the power of provoking the formation and secretion of pepsin, Schiff gave the name of *peptogens*. Among the most effective peptogens were found to be solutions of dextrine, extract of meat (or soup), infusion of green peas, bread (which contains dextrine), gelatine, and peptones. Solutions of grape-sugar, soluble starch, fat-emulsion, or gum, however, had no peptogenic effect; and milk and coffee had not much. Schiff further found that peptogenic substances were just as effective when they were injected into the blood, or into the cellular tissue, or introduced as enemata into the rectum, as when they were introduced directly into the stomach. On the other hand, when peptogens were injected into the small intestine their influence was not observed; their effect seemed to be annulled by some action of the mesenteric glands, or by some change induced in them in their passage along the thoracic duct.

On the ground of these experiments—and they were numerous and oft repeated and gave constant and decisive results—he concluded that the absorption into the blood of these soluble aliments was a necessary preliminary of proteid digestion—that no pepsin or trypsin was secreted unless these substances existed beforehand in the blood. The first act, according to Schiff, of gastric digestion was the absorption from the constituents of a meal of these soluble peptogens by the veins of the stomach. On this followed immediately the secretion of pepsin and the commencement of digestion proper.[2]

These views and experiments of Schiff have not been allowed to pass without challenge, but they have not yet been overturned. If they should be substantiated they will give, curiously enough, a scientific sanction to the prevailing custom of commencing dinner with soup.

The Milk-Curdling Ferment.

You all know that one of the most striking properties of gastric juice is to curdle milk. This property is utilised on a large scale in the industrial art of making cheese. Rennet, which has been used for that purpose from remote antiquity, is simply an infusion of the fourth stomach of the calf in brine. The curdling of casein by rennet does not depend upon the acid of the gastric juice, for it takes place when the milk is neutral or even faintly alkaline. It has until lately been believed that this property was an inherent attribute of pepsin, but this opinion is no longer tenable. Brücke succeeded, by a process I need not particularise, in producing pepsin which had an energetic action on proteids, but which did not possess, except in the feeblest degree, the power of curdling milk. Mr. Benger also found that an extract of pig's stomach in saturated brine, while it possessed energetic action as a milk-curdler, had only feeble proteolytic powers. We must therefore regard the agent in gastric juice which curdles milk as a substance distinct from pepsin.

In the course of my experiments on pancreatic extract, I made the unexpected observation that the pancreas also contained an agent capable of curdling milk. I found this

[1] Most observers have noticed the occurrence of this indigestible residuum (named *Dyspeptone* by Meissner) in the artificial gastric digestion of proteids. I have noticed the same in the digestion of milk by pancreatic extract.

[2] See Schiff's Leçons sur la Physiologie de la Digestion, vol. ii., p. 300 et seq. Paris, 1867.

Digitized by Google

property in the pancreas of the pig, the sheep, the calf, the ox, and the fowl. In whatever way the extract of the gland was made, whatever solvent was used, this property of curdling milk was present in it; but the brine extract exceeded all others in curdling capacity. If a few drops of extract of pancreas be added to some warm milk in a test-tube the milk becomes a solid coagulum in a few minutes. Some minutes later the whey begins to separate from the curd. In short, the action resembles exactly that of calf's rennet; and, so far as I know, you could make cheese with pancreatic rennet as perfectly as you can with gastric rennet. There is, however, not an absolute identity of the two agents. I said just now that gastric rennet produced curdling in neutral and even in faintly alkaline milk; but if the alkali exceed a very small proportion ordinary rennet does not curdle milk. I found that an alkalescence exceeding that produced by one grain of bicarbonate of soda to an ounce of milk altogether prevented the milk being curdled by gastric rennet. But this is not so with pancreatic rennet. You may add two, three, or four grains of bicarbonate of soda to each ounce of milk and still the pancreatic rennet will induce curdling with undiminished energy. Milk is likewise curdled by pancreatic extract when quite neutral, and even when very faintly acid. Indeed, it appeared to me that a very faintly acid milk curdled more actively with pancreatic extract than neutral milk, but not so actively as alkaline milk.

That the curdling agent of the stomach and pancreas is a true ferment, and not some inorganic chemical agent, seems to be proved by the fact that boiling, or even heating to 160° F. (70° C.) instantly destroys its power. I found moreover that, like other soluble ferments, it is precipitated, but not truly coagulated, by alcohol—for it recovers its solubility and activity when the alcohol is removed, even after a contact of several weeks.

The curdling ferment of the pancreas is a distinct body from trypsin, as the following experiments show. (1) Some brine extract of pancreas (which was known to possess strong proteolytic energy) was acidulated with hydrochloric acid in the proportion of 1 per 1000, and then placed in the warm chamber at a temperature of 104° F. (40° C.) for a period of three hours. It was then carefully neutralised with bicarbonate of soda. When thus treated, the extract was found to have lost its proteolytic power, but its curdling action on milk was almost as energetic as ever. (2) A portion of the same brine extract of pancreas was filtered under vacuum pressure through porous earthenware. The filtered product was found to possess an undiminished faculty of curdling milk, but it had almost no power of dissolving the curds. The curdling ferment had evidently traversed the earthenware freely, but only traces of trypsin had passed through.

What is the real function of the curdling ferment? Seeing its striking reaction with milk, one's first idea is that it must have something to do with the digestion of casein. But a little consideration shows that this idea is altogether improbable. Although all mammalia start life on a milk diet, milk does not form a part of the normal diet of any adult creature except man. Nor can its universal presence in the mammalian digestive organs be regarded as a vestigial phenomenon—a "memory" of the suckling phase of their existence—for the same curdling property is found in the stomach and pancreas of the fowl, which never at any period of its life fed on milk. Moreover, it may be doubted whether the ferment in question is the actual agent which curdles milk on its passage into the stomach; for the acid of the gastric juice, which also curdles milk, would probably be beforehand with it, inasmuch as its action is a good deal more prompt than that of the ferment. In the pancreatic digestion of milk, the occurrence of curdling has appeared to me to be a distinct hindrance to the process. Has this ferment any true digestive functions? I think this is quite open to doubt. Its action on milk is apparently akin to that of the fibrin-ferment on blood—and it may likewise have some kindred purpose; but what that purpose may be I am unable to conjecture.

EMULSIVE FERMENT.—DIGESTION OF FATS.

The digestive change undergone by fatty matters in the small intestine consists mainly in their reduction into a state of emulsion, or division into infinitely minute particles. In addition to this purely physical change, a small portion undergoes a chemical change whereby the glycerine and fatty acids are dissociated. The fatty acids thus liberated then combine with the alkaline bases of the bile and pancreatic juice, and form soaps. The main or principal change is undoubtedly an emulsifying process, and nearly all the fat taken up by the lacteals is simply in a state of emulsion, and not of saponification. It is, however, quite certain that both these processes do take place in the small intestine, though in very unequal degrees. The only question in connexion with the digestion of fat which I propose to examine is:—Whether these changes are produced by the operation of a soluble ferment, or by some other and different agencies. In his latest utterances on this subject, Bernard[3] insisted that the digestion of fat, like the digestion of starch and proteids, consisted in the action of a soluble ferment, which he named *Ferment emulsif.* This ferment, he alleged, first emulsified and then saponified fats. In the intestine the change scarcely went beyond emulsion—in this condition fat was found in the contents of the lacteals. Saponification took place almost exclusively further on, and later, in the blood. It is certainly established that the pancreatic juice exercises a marked influence on the digestion of fats, and it is in the pancreas, according to Bernard, that the emulsive ferment is to be found. Bernard demonstrated that healthy pancreatic juice has quite a special faculty of emulsifying fats. Pancreatic tissue has also the same property. If a portion of fresh pancreas be rubbed up with fatty matter and water, you get an emulsion which is fairly persistent. I have not had an opportunity of examining the behaviour of pancreatic juice with fatty matter, and cannot therefore speak of its properties; but it is singular if, as alleged, the effect of pancreatic juice and pancreatic tissue on fat be due to the presence of a soluble ferment, that the extracts of pancreas possess none of the same power. I have made extracts of pancreas in various ways—with simple water, with chloroform water, with dilute spirit, with solutions of boracic acid, of borax, and of both combined, with glycerine and water, with brine, and with solution of salicylic acid, and of salicylate of soda; and yet I could not satisfy myself that any of these extracts possessed any special power of emulsifying fats, nor of liberating the fatty acids and inducing saponification. Paschutin[4] states that the emulsive ferment of the pancreas can be extracted by a solution of bicarbonate of soda. An extract of pancreas made by myself with a 2 per cent. solution of bicarbonate of soda was indeed found to have a very marked emulsifying power, but it had the same power, even in an enhanced degree, after being boiled, which showed that its emulsifying properties could not depend on the presence of a soluble ferment.

I was equally unsuccessful in my attempts to verify the alleged power of extracts of pancreas, and of crushed pancreatic tissue, to liberate the fatty acids. When fresh pancreas, finely triturated with sand, was digested with milk in the warm chamber, I could not obtain satisfactory evidence of the development of free acid from the decomposition of the fat of the milk by a soluble ferment. The pancreas itself yields a slightly acid solution when infused in water, and a mixture of milk and pancreatic tissue always showed a slight acid reaction; but when this primary acidity was neutralised, no further production of acid took place until such a time had elapsed as was sufficient to permit the development of organised ferments and the origination of the lactic fermentation. If the development of organised ferments was prevented by the addition of antiseptics, the mixture of milk and crushed pancreas remained neutral for several days. The same results followed when I operated on emulsions made with crushed pancreas and lard or olive oil. In my numerous observations on the digestion of milk with various pancreatic extracts, I never could detect the production of an acid reaction, unless organised ferments were permitted to intervene.

I obtained similar negative results with almond emulsion. Bernard attributed the formation of an emulsion when almonds (or other oily seeds) were rubbed up with water to the presence in the seeds of a soluble ferment. But I found, to my surprise, that almonds which had been boiled for seven hours still produced a perfect emulsion. As all known soluble ferments are destroyed by boiling, this result seems irreconcilable with Bernard's view. I also found that almond emulsion kept in the warm chamber for six or eight hours at a temperature of 100° F. (38° C.) showed not the slightest evidence of an increase of its original faintly acid reaction.

Digitized by Google

It appeared to be more probable that the fatty matter in the almond existed in the seed in the condition of a solid emulsion, and that the formation of a fluid emulsion by trituration with water was due simply to the liberation of the minutely-divided oil particles, rather than to the intervention of a soluble ferment.

It is with considerable hesitation that I venture to place myself in even apparent contradiction with so great an observer as was Claude Bernard; and I by no means pretend that these observations traverse the main conclusions for which he contended as to the digestive transformations of fat in plants and animals. The views which Bernard developed on the digestive process are based on inductions so wide, and observations so multiplied, that I feel satisfied that their substantial accuracy will be ultimately established in regard to fat, as they have already been established in regard to starch and cane-sugar.

Some observations made by Brücke promise to throw a fresh light on the digestion of fat. Brücke found that oils and fats which contained an admixture of free fatty acids—in other words, which were more or less rancid—were emulsified by a slight agitation with a weak solution of carbonate of soda. J. Gad extended these observations, and showed that even simple contact of a rancid oil with the alkaline solution was sufficient to effect a mechanical division of the oily matter. I have repeated these observations, and the results are certainly remarkable. The different behaviour of two specimens of the same oil, one perfectly neutral and the other containing a little free fatty acid, is exceedingly striking. I have here before me two specimens of cod-liver oil—one of them is a fine and pure pale oil, such as is usually dispensed by the better class of chemists; the other is the brown oil sent out under the name of De Jongh. I put a few drops of each of these into these two beakers, and pour on them some of this solution, which contains 2 per cent. of bicarbonate of soda. The pale oil, you see, is not in the least emulsified; it rises to the top of the water in large clear globules. The brown oil, on the contrary, yields at once a milky emulsion. The pale oil is a neutral oil, and yields no acid to water when agitated with it—in other words, it is quite free from rancidity; but the brown oil when treated in the same way causes the water with which it is shaken to redden litmus paper. I was surprised to find that olive oil (salad oil), which appeared quite sweet, and had not the slightest taste or smell of rancidity, gave a milky emulsion with the soda solution. This oil did not yield any acid reaction to water when agitated therewith. Nevertheless, it evidently contained a little free fatty acid (probably oleic acid, which is insoluble in water, and therefore does not acidify water shaken up with it), for when a portion of this oil was washed with a strong solution of carbonate of soda, and then allowed to separate, the oil thus freed from acid no longer gave an emulsion with the weak soda solution. It would appear that an admixture of only a very small proportion of free fatty acid is sufficient to induce emulsification—a quantity so small as not to cause any appreciable rancidity to the sense of smell or taste. This specimen of almond oil is to all appearance perfectly sweet, but it communicates a rather sharp acid reaction to water shaken up with it, and it gives, as you see, a perfect emulsion with the soda solution.

The bearing of these observations on the digestion of fat is plain. When the contents of the stomach pass the pylorus they encounter the bile and pancreatic juice, which are alkaline, from the presence in them of carbonate of soda. So that the fatty ingredients of the chyme, if they only contain a small admixture of free fatty acids, are at once placed in favourable circumstances for the production of an emulsion without the help of any soluble ferment, the mere agitation of the contents of the bowel by the peristaltic action being sufficient to effect the purpose.

This view of the matter renders it necessary that fresh inquiries should be made into the effect of gastric digestion on fats. It has hitherto been supposed that fatty and oily substances undergo no change in the stomach, but it is quite possible that something may have been overlooked. It was noted by Richet in the patient with a gastric fistula that the fatty matters were detained a long time in the stomach, and that they only passed through the pylorus with the last portions of the meal. It is also a familiar experience to most dyspeptics that rancid eructations are a frequent occurrence in the later stages of gastric digestion. If it should turn out that among the complex operations taking place in the stomach there occurred some slight decomposition of the neutral fats, and a liberation of a small quantity of free fatty acid, such a result would supply the necessary condition for the emulsification of the neutral fats in the duodenum. In speculating on this subject it is difficult to shut one's eyes to the possibility of the intervention of formed or organised ferments in the digestive process. It is well known that fatty acids are liberated in the decomposition of neutral fats by bacteroid ferments (zymophytes), and the presence of ferments of this class in the living stomach has been so repeatedly observed that it may well give rise to the suspicion that they are a normal ingredient of the gastric mucus, and have a normal function to perform in the digestion of some portions of our food. It is not, however, desirable to push speculations of this kind in advance of observed facts, and I only mention them as hints for further inquiry in regard to the digestion of fat.

Lectures
ON SOME
RECENT INVESTIGATIONS
INTO THE
PATHOLOGY OF INFECTIVE AND CONTAGIOUS DISEASES.

Delivered in connexion with the Brown Institution, at the University of London, Dec. 1879,

BY W. S. GREENFIELD, M.D. LOND., F.R.C.P.,
PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTION, ASSISTANT-PHYSICIAN AND LECTURER ON PATHOLOGICAL ANATOMY TO ST. THOMAS'S HOSPITAL.

LECTURE I.—PART IV.

HAVING thus described the principal generic forms of bacteria, it must suffice for me to say but little of their conditions of life and of the effects produced by their growth. As yet we are but on the threshold of our knowledge of bacteria, and, investigations having been made only on a very restricted number of species, we do not know how far the results are true of other species. I shall have to mention some points with regard to certain species when speaking of their action in the animal body: a brief outline of some main facts is all that time will now permit.

Speaking generally, all bacteria require for their growth the presence of suitable nitrogenised pabulum, the supply of oxygen, and the maintenance of a suitable temperature; and their free development depends on the sufficiency of these conditions. It has been shown, however, that they may slowly undergo vital changes if oxygen be in defective quantity. Many conditions either impair their vitality or cause their death. Heat and cold have marked effects. For some bacteria the range of temperature suitable for free growth is very restricted; probably not for all. But their tenacity of life under the influence of heat is great, and this is especially the case with the spores when exposed to a dry heat. The exact thermal death-point in fluid of the fully-developed organisms has only been ascertained with regard to one or two species, but all are apparently destroyed at a temperature much below 212° F. Some spores resist even this temperature, though only for a short time, and in a dry state may survive nearly 300° F.[1] The effects of cold have been less fully ascertained, but a temperature below freezing is not destructive of bacillus anthracis. A pressure of twelve volumes of oxygen destroys the life of spores of bacillus anthracis (Ewart). Many apparently slight causes interfere with the development of the common bacteria of putrefaction. Very minute quantities of many "antiseptic" substances do this. Wernich's experiments render it probable that bacteria themselves in their growth produce minute quantities of aromatic subetances, which, unless removed as soon as formed, act as antiseptics, and

[1] For some interesting details of the effects of high temperature on germs of monads not far removed from bacteria, see Dallinger, in the Journal of the Royal Microscopical Society, Feb. 1880.

Digitized by Google

hinder further development.[2] Skatol, indol, kresol, and phenol are amongst these bodies. The experiments of Downes and Blunt,[3] which have not, so far as I am aware, been either controverted or confirmed, seemed to show that exposure to sunlight sterilised some cultivations of common bacteria, and that a vacuum had the same effect on urine and on Pasteur's solution. Again, it is now well known that the lower orders, common putrefactive bacteria, war against the higher, and that the growth of micrococci and bacteria arrests the development of the more highly-developed and endowed bacilli.

With regard to the vital reactions of bacteria, all recent research seem to show that bacteria are the active agents of fermentation of albuminoid bodies, and that, widely distributed as they are, everywhere swarming in countless myriads, yet the microzyme concerned in any particular process of the kind is probably limited to that process. The remarkable experiments of Professor Lister on lactic fermentation constitute one of the most conclusive pieces of evidence on this point.[4] But whether the action of the bacteria is directly due to the changes in composition caused by their growth, or to some excreted product produced in that growth, is not certain. We shall see that a similar question presents itself in relation to the pathological effects of bacteria and bacilli. I need hardly remind you that many of these points were discussed in detail by my predecessor, Dr. Burdon Sanderson, in his last course of lectures in this place. I must for the present leave this part of the subject and consider some of the views which have been held as to the relations of bacteria and allied organisms to contagion, and the methods and results of researches made with the view of ascertaining those relations.

VIEWS AS TO THE RELATION OF BACTERIA TO CONTAGION.

It is not unnatural to start with a presumption in favour of the view that, if bacteria (using the word in its widest sense) have anything to do with the production of specific diseases, they are not merely the essential morbific element or contagium, but that for each disease of the class of infective and contagious there is a separate organism, which, so far as we know, must retain its characters and be incapable of transition into any other analogous organism. If, for example, the two diseases, small-pox and measles, are each due to the action of a lowly organism of specific nature, our knowledge of those two diseases enables us to affirm with confidence that, however they may have originated in the first instance, they have maintained for some scores of years at least the same characters, that the cycle of organic change which results from the contagium of small-pox is not only definite in character, but bears the same relation to time in thousands of cases under the most dissimilar conditions of race and character, and that with rather less exactness the same is true of measles. Now, if this cycle of systemic change is directly dependent on some specific organism, it follows that the organism itself retains its properties, follows the same laws in its multiplication and reproduction in each case, and does not depart from these characters during a long succession of generations.

Hence, if we once admit that each distinct contagious disease is dependent on a lowly organism, we are led almost irresistibly to conclude that each of these organisms or contagia is a separate species. And, then, if we consider that the soil and climate—i.e., the human or animal body and its conditions—are the same for two different disease-organisms, we must, I think, be led to conceive that each organism has not only a different life history, rate of development, tendency to flourish in a particular soil—i.e., part of the body, &c.; but that distinct morphological characters may also be anticipated to exist, and that these characters may be recognised, if not in all stages of the growth of the organism, yet at some period; or by a comparison of the whole series of changes which it undergoes when grown under favourable conditions.

However crude these conceptions may be, and however little they may stand the test of a critical examination, even from a speculative or metaphysical point of view, there can be no question that such ideas most naturally present themselves to one's mind when brought face to face with the subject; that they represent the view taken by a large majority of the medical profession who have paid any attention to it; and that they have dominated, and do still dominate to a large extent, those who have made special investigations into the life history of contagia. For if this view be correct, or even approximately so, we may be able not only to isolate the organism upon which each disease depends, but we may be able to cultivate it under suitable conditions; we may draw its form, measure its size and that of each of its constituents; we may ascertain under what conditions it will grow and develop, and, what is perhaps of the highest importance, how its growth may be checked by such means as will not be deleterious to the animal body, and thus lay the foundations of a true preventive medicine.

In the first instance, then, the impulse of every one will be to search in the tissues after death for organisms, to describe their characters and differences, and their position in the several organs of the body. Then the blood and lymph, and the discharges which are known to hold the contagium, will be studied during life, and by means of cultivation, under suitable conditions, either in fluids which may afford material for their growth, or by inoculation of animals, we shall attempt to reproduce first the organism, and then by means of it the disease.

One cannot but be fascinated by such a study, by the prospect of thus tracking disease to its origin, of holding in one's hand the contagium vivum, of measuring under the microscope the size and watching the growth of each separate disease in its potential seed. Moreover, the prospect seems the only one which affords us any chance of being able by the microscope to distinguish the contagia of diseases which leave so little trace in the body as typhus or scarlet fever; if this does not aid us, how shall we penetrate more deeply into the intimate causes of these mysterious and deadly changes which cut short so speedily the life of the body?

METHODS OF OBSERVATION.

In the investigation of the various infective and contagious diseases, in order to ascertain their relation to the lower organisms, certain methods have been adopted which are common to all the forms of disease. Though well known to many of you, it may, I think, be advantageous to describe them, and to point out some of the difficulties which may be encountered in their application. It is right that we should also try to estimate them at their true value as means of discovery.

Let us take as an instance any infectious or contagious disease—such, for example, as small-pox. Now we know that the infectious power in many diseases resides in certain of the lesions, though not limited to them. The matured vesicle in vaccinia, the pustule in small-pox, the throat exudation in diphtheria, the nasal mucus in glanders, the chancre in syphilis, are practically, in the majority of cases, the source of active contagion. But we must also bear in mind that modern researches have shown that the infecting property is not limited to these more external parts, but in many cases is widely diffused through the body, though not in positions in which it can of itself become active, so that our researches must not be limited to the more obvious channels.

Now, starting with the hypothesis that the contagium is of the nature of an organism having an independent existence, but only growing under favourable circumstances, such as of soil, warmth, and other physical conditions, we should expect, if the hypothesis were correct, that we might—(1) be able to discover the organism by visual examination; (2) if we could imitate artificially the necessary conditions, for its growth and reproduction, we might, by growing successive crops of the deleterious organism, succeed in again producing the disease from a distant generation. Moreover, if we found that the organism was constantly present in the infective material, and was reproduced in a second case propagated from a distant cultivation from the *materies morbi* of the first, we should expect to find in the body the course of its transit from the site of inoculation to the secondary site of production of infection; and if the sources of infection were numerous, we might, I think, reasonably expect to find the organism widely diffused in the body. I will go further, and say that I think we might reasonably expect that if there are numerous secondary lesions there should be some definite and discoverable (I do not say discovered) relation between the lesions and the presence of organisms, as well as the constant presence of the latter.

Digitized by Google

The microscopic examination of the contagious material has been made in a large number of diseases without, in most cases, any very decisive results. Such as have been attained relate chiefly to the infective diseases. But we know that these may be, and probably are, multitudes of organisms which, either themselves or their seeds, are beyond the reach of our present microscopes, and what has yet been successfully accomplished in seeing organisms which till lately remained invisible, makes it impossible to say that others far smaller do not exist. The microscope, therefore, does not help us beyond a certain point.

The method of fractional cultivation, first introduced, I believe, by Klebs, consists in growing artificially in a suitable fluid a minute quantity of the contagious material, and transplanting successively minute portions of the cultivation to fresh fluid. In order that this method should be successful, there are certain essential conditions, failing which, the results may be entirely fallacious. And even under the best conditions, this method is only of value within certain limits.

That the cultivating fluid should be one capable of supporting the life of the organism, that it should itself be free from organisms, and incapable of generating them under the conditions in which it is placed, are, I need not say, essentials. Our experiments may fail owing to the want of proper nutritive matter in the fluid, or to the absence of the right degree or duration of heat. We can only very roughly imitate the natural conditions of the body.

But let us suppose that by thus inoculating cultivating fluid with contagious material, we have succeeded in producing a definite organism, and by successive inoculations transferring it from one stage to another in a continuous series. To give our results a definite value in the explanation of contagium, we must again reproduce the same disease by inoculation of our ultimate product, and we must take precautions to prevent any possibility of exposure of the inoculated animal to contagion from other sources, or conveying a diluted contagium in our successive cultivations. Easy as these precautions may seem in theory, they are in practice very difficult of accomplishment, and I believe many errors have been made in consequence. With some bacilli of recognised form, and having very definite changes, we may follow their development step by step with the microscope. But in all the fluids which support bacterial life, we are liable to get the accidental introduction and growth of the commoner forms, the germs of which are everywhere present in the air, or of rarer forms present in certain places. Of course, as soon as these are recognised, the specimen is eliminated, and cast away as worthless, for not only do these bacteria introduce a new element, but they are inimical to the development of most of the more stable and highly-developed forms. But we cannot take the same steps to eliminate from our series all other rarer forms of bacteria, the germs of which may be present in certain atmospheres. Herein, too, lies another difficulty, the importance of which has been especially insisted on by Koch—namely, that in the case of bacilli, such as those which he found in the artificial septicæmia of mice, which are so minute as to be recognised only with difficulty, or by means of staining, it is practically impossible to watch the successive developments in such a way as to reject all the sources of error. We may try to do so by withdrawing a small quantity of the fluid with a capillary tube, but each time we do so we run the risk of the entrance of other germs, and multiply indefinitely our chances of failure. It follows that this method is scarcely applicable to organisms too small to be readily recognised and watched.

Supposing, then, that in our cultivation we do not find any visible development of organisms, we may nevertheless persist in our efforts by continuing to inoculate successive quantities of fluid, and eliminating all those in which organisms appear; and, finally, we might be able to reproduce from an apparently unaltered fluid the original disease. At present we should not thus have gained any information as to the relation of lower organisms to the contagium; we might merely have diluted it, or have succeeded in setting up certain changes in the fluid, capable of producing a deceptively similar blood-poisoning. If it were an acute specific disease, the latter should not be a source of fallacy, but it would hold good for septicæmia.

So that this method of fractional cultivation is applicable where we can produce visible and recognisable forms of life, and reproduce the disease from them, having excluded the sources of fallacy of mere dilution of contagium. But the failure then to produce visible organisms does not negative their presence and potency. Nor does the failure to produce the disease from the organism prove its non-relation to the contagious process, for the quantity of the contagium may be insufficient; it may be in an inactive form, requiring a certain degree of active development to acquire its potency, or the animal inoculated may be insusceptible, or other causes may interfere.

Time will not permit me to describe the methods which are adopted in the cultivation and the study of bacteria, and the search for them in the tissues and fluids of the body. I hope to be able to demonstrate some of these at a later period, but so much depends on minute detail, and there are so many ways of arriving at the same result, that it would be wearisome to discuss the various methods employed by different observers. Moreover, these several methods are described in detail by most writers on bacteria, to whose works I have already referred.

LIVER ABSCESS AND ANTISEPTIC PARACENTESIS.

BY SIR J. FAYRER, M.D., F.R.S.

THE cases on which the following remarks are based present clinical features of considerable interest in relation to disease which though most commonly met with in India, China, the tropics, sub-tropical or other hot and malarious regions, is not unfrequently seen here in persons who have returned from those climates, but not always with a very definite appreciation of the nature and cause of the loss of health.

The symptoms are sometimes so obscure as to render diagnosis uncertain, and treatment consequently unsatisfactory. I know of few things more difficult in certain cases than the detection of pus in the liver; and it is often long before any certain conclusion can be formed on the point. It may be, indeed, not during life. I shall refer to some points of practical interest in relation to this subject, the time when, and the place where, exploration or paracentesis should be performed.

I had punctured liver abscess in India antiseptically; but this was the first occasion in my experience in which the proceeding was conducted with all the precautions insisted on by Mr. Lister, who in this case himself performed the operation, and I am sure he must have been gratified with a result which affords corroborative evidence, were any needed, of the benefits to be derived from antiseptics. I gladly take this opportunity of expressing my appreciation of the value of a system which promises to include this dangerous form of abscess in the ever-widening sphere of its utility, and of thanking him for the kindness with which he so materially contributed towards the successful issue of a case that will be a guide and precedent in dealing with others of a similar nature; for it seems to show that paracentesis may be safely practised under the protecting influence of antiseptic spray, when otherwise the operation might be deemed questionable, if not altogether inexpedient, and that it may thus curtail the exhaustive process of disease which, if left to itself, a liver abscess entails, and save life that otherwise would have been lost.

On the 11th December, 1879, I was asked by Dr. Anderson, of Maida Vale, to see a young officer, aged twenty-three, who had recently returned from India. I found him with well-marked symptoms of liver abscess, and much exhausted by a fatiguing journey from Bombay. There was increased hepatic dulness with enlargement, chiefly upwards, and bulging of the lower right side of the thorax, but the intercostal spaces were not then protruding. He was much depressed, in great pain, was slightly jaundiced, the tongue brown and coated, was unable to lie on either side, had nausea and cough, had lost all appetite, and was unable to sleep. There were occasional rigors and profuse night-sweats. The urine was high-coloured, full of lithates, not albuminous. The evacuations were scanty, frequent, and

Digitized by Google

clay-coloured. He was much emaciated, and presented a miserably worn and cachectic appearance. From his history and actual condition it appeared to me that suppuration was approaching the surface upwards through the diaphragm and thoracic parietes, but did not demand immediate interference in his exhausted condition. I therefore recommended that he should be allowed to rest, be carefully nursed, and that the bowels should be regulated with bitter saline laxatives, quinine given, poultices and fomentations applied over the liver, and that sedatives sufficient to insure sleep and rest should be administered, that he should be fed on milk and light farinaceous diet, and a very moderate amount of stimulants given, and any change at once reported to me.

I saw him again on the 18th December, and found the symptoms of liver abscess more pronounced; the bulging of the side had increased, and there were slight œdema and obscure fluctuation in the seventh intercostal space between the mammary and axillary lines. The jaundice was perhaps slightly diminished, but other symptoms continued much the same. Rest and careful nursing had otherwise ameliorated his condition. I recommended that the abscess should be opened without delay; and as it seemed a favourable case for antiseptic treatment, I requested Professor Lister to perform the operation, which he most kindly did, in conjunction with Mr. R. Godlee, on the 19th December. Under the influence of chloroform an incision was made through the most prominent part of the bulging of the intercostal space; it was deep, and gave rise to rather profuse hæmorrhage of dark blood, showing that vascular liver substance had been divided. This caused some anxiety for a moment or two, but bleeding soon ceased, and about twenty ounces of dark, blood-stained pus issued without any pressure, the spray being carefully directed on the wound meanwhile. The antiseptic gauze and bandages were then applied. He seemed much relieved by the operation, and expressed himself as feeling better than he had done for months.

The following notes of the history and progress of the disease, from its commencement up to the date of recovery, are by Dr. Anderson:—

CASE 1. *Summary of the Case of Lieutenant W——, aged twenty-three and a half years; five years and two months in India.*—"In November, 1878, when at Hyderabad, Scinde, Lieutenant W—— suffered from a very severe attack of fever and hepatitis, necessitating his proceeding to Kurrachee for change of air. Soon after his arrival there the regiment was ordered on field service in Afghanistan, and as his health was in some measure restored he accompanied it. During the cold weather he enjoyed fairly good health, but suffered whilst on the march from Jacobabad to Dadur from severe attacks of ague, with much gastric disturbance, on several occasions. In May last, at Dozan, in the Bolan Pass, having for some time previously undergone much fatigue and exposure to the sun, he had an attack of hepatic congestion followed by jaundice. This yielded to treatment, but left him very weak and anæmic. He was, however, gradually recovering strength, when he was again attacked (on 19th September) by acute hepatitis, accompanied by much prostration and total loss of appetite. He said he had had diarrhœa for eight months with traces of blood. The acute symptoms subsided under the administration of ammonium chloride and taraxacum with mustard poultices and hot fomentations to the side, but his strength was greatly reduced, and as the regiment was under orders to proceed to the Pishin at an early date, and Lieutenant W—— was quite unfit to undergo the hardships and exposure of field service, he was sent on six months' leave to India.

"On Oct. 3rd Lieutenant W—— left Dozan, and arrived at Kurrachee on the 23rd of that month, travelling in rough carts all but the last day in rail. During his stay there, he had rigors, fever, and cold sweats. He went before a Medical Board on the 25th, and obtained sick leave to England for two years. Two days after he went by steamer to Bombay to await the departure of a troop-ship. In the hope of a change of climate effecting improvement, he left Bombay on the 8th November, and after a very trying voyage, having had rigors and pains, he observed bulging in his side at Malta. He reached Portsmouth on December 8th. During the voyage he was under the care of a medical officer who administered quinine and nitro-muriatic acid, and ordered poultices, hot fomentations, and belladonna plasters, to allay the severe pain, but with little effect.

"Lieutenant W—— arrived in London on the 9th of December, very feeble, and unable to walk. He was suffering from jaundice, and complained of very severe pain in his right side, which was constant, and prevented him from obtaining rest. His appetite was gone, his tongue was furred and brown, his motions were clayey, and he suffered from profuse night sweats, with occasional rigors. To relieve the pain opium and bromide of potassium were administered freely, and poultices applied locally, but with only momentary benefit. On the 11th it was found that the hepatic dulness extended over a larger area of the chest than normal, and that there was considerable bulging of the right side just over the seat of pain. Recommended that he should be carefully watched, the poultices to be continued, as well as the sedative draughts; also that quinine be given every four hours, and the bowels kept open (with sulphate of magnesia). Between the 11th and 18th of December the same treatment was carried on; the night sweats and rigors increased; the temperature varied from normal to 101°, the pulse was rapid and feeble. On the 19th he recommended immediate steps to be taken for an operation.

"On the following morning Professor Lister (Sir J. Fayrer being present), assisted by Mr. Godlee, operated by making an incision about an inch and a half long in the intercostal space, and three inches external to the nipple, cutting straight down on the abscess. About twenty ounces of pus were removed, an india-rubber drainage-tube left in the wound, and over this a large dressing of antiseptic gauze.

"Dec. 20th.—He has improved in every way; little or no pain; had a good night's rest, the first for many months. Appetite improved, tongue cleaner, no sweats, temperature and pulse normal. Dressing changed; gauze stained through to gutta-percha sheeting; no pus (?).

"21st.—Slept well; appetite ravenous, but food given with caution. Temperature and pulse normal. Dressing changed; discharge considerable, but still no pus (?).

"22nd.—No pain; can sleep on either side; motions natural; appetite good; dressing changed; discharge much less; no odour; temperature and pulse normal. For the next week the dressings were changed every other day, as the discharge decreased. On Christmas-day he was able to sit in an arm-chair for a couple of hours.

"Jan. 3rd.—Doing well; has gained flesh; able to walk about. Dressing changed; only tinged with sanguineous discharge; drainage-tube shortened.—Jan. 7th: Able to go downstairs; appetite very good; no trace of jaundice; tongue clean; dressing changed; no discharge; drainage-tube cut.—After the 7th he had his side dressed only once a week; improved rapidly in strength, and on the 16th of February the drainage-tube was removed.

"From the date of the operation he has had no bad symptoms, with the exception of a slight attack of ague, for which five-grain doses of quinine were given with good effect. He has gained more than a stone and a half in weight during the last two months."

On the 9th March he appeared before the Medical Board, the wound healed and his general health restored; but, considering his history, immediate return to India is not desirable.

This is a good example of the ordinary tropical abscess, due to climatic influence and exposure. The points of interest in the case are the position of the abscess and the direction upwards in which it pointed, the period at which it was opened, the results of antiseptic treatment, and the rapid recovery; the presence of jaundice is also noteworthy, that not being a common accompaniment of this form of abscess; and its rapid disappearance after evacuation of the matter, on pressure being removed. It is satisfactory when liver abscess comes to the surface *below* the *costal cartilages*, as there is less danger in opening it through the abdominal than the thoracic parietes. Adhesion may generally be assumed to have taken place, and danger of extravasation is avoided; but when it points upwards, there is more danger, especially when it takes place high up, lest there should be effusion into the cavity of the pleura, or possibly even danger of wounding the lower margin of the lung where it overlaps the liver, though it is probable that this would be consolidated with the pleura and diaphragm into one mass. In the case cited the incision must have passed very near, if not actually, through the margin of the lung. That liver tissue was divided was evident from the profuse hæmorrhage, which ceased, however, very quickly, seeming to show that it is not of much importance so long as there is no extravasation into the cavities. The rapid recovery

Digitized by Google

seems to show that the abscess was single, and that cicatrisation had occurred.

I have punctured liver abscesses, and washed out the cavity with solution of carbolic acid, with good results; but am convinced that the method adopted in this case is preferable, and that neither washing out the cavity nor pressure is needed. With antiseptic precautions there is little tendency to the formation of more pus, whilst the residuum finds exit through the drainage-tube; no local irritation is excited, and if the inflammatory condition which originally caused suppuration have passed away, a sanious discharge only follows, and repair may be expected gradually to go on. In the event of a second abscess forming the case would be complicated; but even then the prospects of recovery would be greater under the antiseptic treatment.

The so-called tropical abscess of the liver appears to be a result of climatic causes, to which some constitutions are more prone than others; in certain instances, aggravated, no doubt, by injudicious eating and drinking, though it may happen in those who have observed the greatest moderation. Some individuals seem to be so susceptible as to be totally unable to tolerate the climate, and though perfectly healthy in temperate latitudes, become affected by liver-disease directly they return to India. I have been compelled, reluctantly, to invalid officers on this account, attempts to resume work in India, after recovery at home, having resulted in immediate recurrence of the disease.

Tropical abscess is generally single, but not invariably so, and though always a very dangerous disease, is less so than pyæmic liver abscess, which is multiple; for if the contents can be evacuated either by spontaneous or artificial means, recovery is not only possible but probable, provided that the active condition of the disease which determined suppuration has ceased, and purulent infection has not taken place. It is a disease to which Europeans are more liable in India and China than in the West Indies or other tropical stations, and is a fertile source of invaliding and mortality, as you will gather from the following extracts from the Indian Army Sanitary Report:—

European troops in India, 1877.—Strength, 57,260; admission for hepatitis, 2490; invalids for change, 300; invalids for discharge, 22; deaths, 93.

For five years, 1871–1875, there were 1868 men invalided from the Indian army, for hepatitis.

India, 1878.—Strength, 56,475; admission for hepatitis, 2461; deaths, 127; invalids for discharge, 34; invalids for change, 285.

I find in Bryden's "Vital Statistics," that of the British army in India up to 1876, for a period of six years—viz., 1871–1876,—out of an aggregate of the average annual strength of European troops for that period:

Bengal	219,290
Bombay	63,279
Madras	67,451
Total	350,020

The average annual admission-rate for hepatitis per 1000 on the six years was—

Bengal	49·7
Bombay	44·0
Madras	70·8

That the deaths during that period were—

Bengal	427
Bombay	124
Madras	218
Total	769

That the death-rate per 1000 men was:

Bengal	1·95
Bombay	1·90
Madras	3·28

There were invalided—

Bengal	1354
Bombay	337
Madras	538
Total	2229

Or at the rate of per 1000:

Bengal	6·17
Bombay	5·33
Madras	7·98

This shows that the liability to death from hepatitis is much higher in Madras than in Bengal or Bombay, which are less tropical than the stations in Madras. The subjects of these statistics are for the most part young and healthy men. The European army in India is, in fact, a young one, only 2 per cent. being over forty-six years of age, and only 14 per cent. above thirty-five. 86 per cent. of the total are men below thirty-five years old, 65 per cent. are under thirty, whilst the restrictions placed of late on sending young immature soldiers to India have resulted in this, that the returns for 1875 show only 1264 lads under twenty, and those of 1876 only 1185. The cases returned under hepatitis are not, of course, all of abscess; many, no doubt, are due to congestion or other disease; but it is probable that a large proportion of the fatal cases were due to suppurative hepatitis. Many of them, it may be presumed, terminated sooner or later either in death from continuance of disease, or recovery after getting rid of the abscess by spontaneous evacuation, or by surgical interference. The records of Netley and other large hospitals would supply evidence of the means available in this country for studying the course and termination of tropical hepatic abscess.

(To be continued.)

ON REMOVAL OF THE TONGUE BY MEDIAN DIVISION.

BY W. MORRANT BAKER, F.R.C.S.,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, AND SENIOR SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

(Concluded from p. 560.)

THE following form the whole number of hospital cases in which I have removed the tongue, in part or wholly, by the method of median division with the knife, and subsequent application of the écraseur; but I may add that since my earlier cases the method has been adopted by most of my colleagues at St. Bartholomew's Hospital; and to them, not less, I believe, than to myself, it has seemed the best method of operating, when at least half the tongue must be removed, and when it is not considered advisable to divide the lower jaw.

For the details from which the following brief abstracts have been made I am indebted to the records of the surgical registrars, Mr. Butlin and Mr. Macready.

CASE 1.—Emma S——, aged thirty-seven, was admitted into St. Bartholomew's Hospital on Sept. 28th, 1876, on account of ulceration of the left side of the tongue. About three years before her admission a small fissure was noticed on the side of the tongue, but she took little notice of it until a few months ago, when it began to increase rapidly in size. Her general health is good. On the left border of the tongue is a raised ulcer with indurated base, measuring about one inch in length by half an inch in breadth. It extends to the level of the last molar tooth, but the finger can be got behind it to healthy tissue. The tongue is not adherent to the surrounding parts. There is no lymphatic glandular enlargement. On Oct. 7th the diseased part of the tongue was removed by Mr. Baker, the method adopted being that of dividing the tongue along the middle line, and afterwards looping a wire écraseur around the left half. There was not much hæmorrhage. The after-progress of this patient was very satisfactory until Oct. 17th, when she began to complain of sore-throat and tightness of the chest. On the following day (the 18th) the patient was worse, with a temperature at 8 P.M. of 104·5°. She had a harsh cough and great dyspnœa.—Oct. 19th: Temperature 104°; the urine is loaded with albumen, and has a specific gravity of 1038. About 6 P.M. the patient died quite suddenly, as if from asphyxia.

The post-mortem examination disclosed the presence of thick yellowish-white membrane on the mucous membrane of the tonsils and neighbouring parts, which could be easily peeled off; while a similar membrane covered the whole of the epiglottis, and extended to the vocal cords. About this point the membrane ceased abruptly, but was found again at the bifurcation of the trachea, extending into each bronchus, and thence into the smaller bronchial tubes in each lung. The right bronchus was completely blocked, for

Digitized by Google

the membrane had become detached above, and had fallen down into the bronchus—this event being, without doubt, the cause of the patient's sudden death. When drawn up the membrane formed a long, continuous tube, which fitted accurately the interior of the trachea up to the point at which, when traced downwards, it had been found wanting. In other respects the lungs were in a fair condition. The kidneys were cloudy and congested.

Nothing was subsequently discovered in explanation of the diphtheritic condition which caused the patient's death. The ward in which she lay had been quite recently thoroughly cleansed, and in some parts remodelled.

CASE 2.—William B——, aged sixty-four, was admitted into St. Bartholomew's Hospital, May 22nd, 1877, on account of cancer of the tongue. About an inch behind the tip is an epithelial cancerous ulcer, with an area nearly as large as half-a-crown. The base is deeply excavated and covered by a greyish slough. The borders of the ulcer are red, nodulated, everted, and hard; the hardness extending into the floor of the mouth in the neighbourhood. Two small glands can be felt enlarged beneath the chin. The patient is a pale, ill-nourished old man. He suffers great pain both in the mouth and in the left side of the head. He has great difficulty in speaking, and saliva is continually running from his mouth. Urine, sp. gr. 1015, acid, albuminous.—May 26th: The whole tongue was removed with a whip-cord écraseur; the organ having been first incised and slit along the middle line, and each half being taken away separately.—June 10th: The patient has done well, and the wound is now healed. He was sent to the Convalescent Hospital June 22nd. When seen several weeks afterwards the mouth remained quite well.

CASE 3.—(The following case has but little bearing on the subject of the present paper, inasmuch as the operation was performed merely for the purpose of lessening the size of a large ulcerating mass of cancer of the tongue, which had extended far beyond the possibility of complete removal before the patient's admission into the hospital.)—Aug. 27th, 1877: Dennis C——, aged forty-five, felt pain in the right ear, which was followed by a swelling in the parotid region of the same side, about four months ago. Two months later the tongue became very sore, swollen, and painful, and has become gradually worse up to the present time. He feels sure that the swelling in the neck began before the tongue gave him any trouble. Now there is an irregular, nodulated, hard swelling in the right parotid region, extending to the submaxillary region, and downwards in the neck. The right side of the tongue is exteriorly affected by an ulcerating mass of epithelial cancer, and the finger cannot be passed beyond the limits of the disease.—Sept. 1st: All the teeth on the same side as the disease, which seemed likely to be a source of pain and irritation, were removed at this date.—12th: The patient still complained of intense pain both in the mouth and on the side of the head; and as a means of temporary relief the tongue was divided by a median incision, and the right half was removed. Only a portion of the diseased tissue could, however, be taken away.—14th: He has rather less pain than before the operation; but still complains of occasional violent shooting pain over the side of the head.—15th: At 8 P.M. last night the patient had a severe rigor. Temperature 102°, pulse 120.—19th: The patient died today, after well-marked symptoms, during the last four days, of septicæmia.

CASE 4. — Nov. 26th, 1877: George D——, aged sixty-two, a clerk, was admitted into St. Bartholomew's Hospital on account of an ulcer on the right side of the tongue, which began as a small lump in September last, and, as he thinks, in consequence of the irritation produced by a jagged tooth. The lump quickly increased until a fortnight ago, when it gave way and became ulcerated. The ulcer has also rapidly enlarged. Until lately his general health has been always good. The right border of the tongue, from about one inch behind the tip, and for the length of at least two inches, is now occupied by a foul irregular ulcer, having an exceedingly widespread and indurated base, and raised and thickened edges. The induration extends nearly as far back as the finger can reach, but does not extend much into the floor of the mouth, nor apparently to the middle line of the tongue. There is no lymphatic glandular enlargement. — Nov. 28th: Mr. Morrant Baker removed the right half of the tongue with a wire écraseur, after dividing the organ along the middle line with the knife. The disease extended as far back as the anterior arch of the palate, which was divided to facilitate the operation. — Dec. 3rd: There has been no trouble since the operation. The patient is doing well.—11th: Discharged from the hospital, well.

Postscript.—Within a few months after the operation an enlarged gland appeared, deeply seated in the right side of the neck beneath the angle of the jaw, and gradually increased. For some time, however, it gave the patient very little trouble; but at length it more rapidly enlarged and fungated, and the patient died in December, 1878. To the time of the patient's death (more than a year after the operation), the mouth remained perfectly healthy, with no sign of recurrence of the disease.

CASE 5.—George S——, aged forty-four, was admitted into St. Bartholomew's Hospital, May 22nd, 1878, on account of cancer of the right side of the tongue. An epithelial cancer was removed from the site of the present disease by Mr. Morrant Baker, December 26th, 1873 (nearly four years and a half ago). The scar remained quite sound until two months ago, when it became sore, and has been very painful ever since. The scar is opposite a sharp-edged tooth in the lower jaw, which causes him a good deal of pain. He has pain also when he eats, and his rest at night has been much disturbed. On the right side of the tongue, near the front, is a puckered scar, covering a space about as large as a shilling. Its borders are indurated and nodular, and its lower edge extends into the floor of the mouth. The surface is superficially ulcerated, and has patches of white thickened epithelium scattered over it. There is no lymphatic glandular enlargement.—May 25th: The whole tongue was removed by Mr. Baker. The frænum linguæ and mucous membrane of the floor of the mouth were divided with part of the genio-hyoglossus muscle, and the tongue was then incised along the middle line, and the loop of an écraseur was slipped over each half. The mucous membrane of the floor of the mouth, where it was encroached upon by the border of the ulcer, was carefully separated from the lower jaw as widely as possible of the disease.—June 21st: Nothing specially worthy of note occurred after the operation, and now the wound has quite healed.

CASE 6.—Nathaniel W——, aged fifty, an engine-driver, was admitted into St. Bartholomew's Hospital on Sept. 12th, 1878. Eight or nine months ago a pimple formed on the right side of the tongue near the tip, the patient's attention having been drawn to it by smarting after smoking a strong pipe. Of late it had ulcerated and rapidly extended. An epithelial cancer now extends along the right side of the tongue from the tip to the level of the circumvallate papillæ, but does not extend to the floor of the mouth. The surface and edges of the ulcer are now extremely hard, and a lymphatic gland just below the parotid is enlarged. The whole tongue was removed soon after the patient's admission, an incision having been made along its raphé, and the two halves removed with wire écraseurs after the connexions of the tongue in the floor of the mouth had been in great part severed. On Oct. 8th the wound had quite healed, and the patient was discharged.

Postscript (June 30th, 1879).—The patient was seen at this date (nine months after the operation). The mouth remained perfectly healthy, with no sign of recurrence. The lymphatic glands in the submaxillary and parotid regions were greatly enlarged and hard, and the facial nerve on this side was evidently paralysed.

CASE 7.—Edward D——, aged fifty-six, was admitted into St. Bartholomew's Hospital December 3rd, 1878. He was quite well until September last, when he first noticed a sore place below the tongue on the left side. It has gradually increased ever since. On the left side is a foul, irregular ulcer, involving the tongue and floor of the mouth, and extending to the lower jaw. The tissues around are much indurated, and the ulcer extends as far back as the last molar tooth on the same side. Its whole extent cannot be easily made out, on account of the way in which the tongue is bound down by adhesions. There is no lymphatic glandular enlargement.—Dec. 14th: Mr. Baker removed the whole tongue. The left cheek was first divided from the anterior border of the masseter muscle to the angle of the mouth, and the tongue was then freed from its connexions in the floor of the mouth. The diseased mucous membrane of the last-named part was also carefully gouged away from the gum at the part at which the disease had encroached on this structure. The tongue having been then incised along the middle line nearly as far as the epiglottis, and the separation of the two halves completed with the finger, an écraseur was applied over each half, well beyond the limits of the disease. After the removal of the

Digitized by Google

tongue the wound in the cheek was brought together with a harelip-pin and a couple of silver sutures. With the exception of a moderately-severe attack of erysipelas, the patient did well after the operation, and was discharged from the hospital with the mouth soundly healed.

CASE 8.—Thomas P——, aged forty-five, a butcher, admitted into St. Bartholomew's Hospital on the 10th of January, 1879. Six months ago he first noticed a small sore on the left side of the tongue, which has since steadily increased. Within the last fortnight a swelling has appeared beneath the jaw, just behind the angle. There is an epithelial cancer extending along the left border of the tongue from near the tip to the last molar tooth. It is covered by a greyish-yellow thin slough. The edges are raised and everted. Its base and the greater part of the tongue are very firm. The submaxillary lymphatic glands and the glands in the parotid region are much enlarged and hardened.—Jan. 18th: Mr. Baker divided the tongue along the middle line, and removed the left half with the écraseur. —21st: Has passed better nights since the operation than for some weeks previously.—Feb. 15th: The wound has soundly healed. The swelling of the lymphatic glands in the neck has much increased, and now there is swelling on the right side. He has no pain in the mouth.

CASE 9.—John H——, aged fifty-two, a shoemaker, was admitted October 28th, 1879. About ten weeks ago he first noticed a sore spot on the left border of the tongue, which has gradually increased in size to the present time. About the middle of the left edge of the tongue is an irregular oval epithelial cancerous ulcer, with a raised and hardened base, and clean surface. A small hardened lymphatic gland can be felt beneath the jaw on the left side.—Nov. 1st: The whole tongue was removed by Mr. Morrant Baker. Its connexions in front and at the sides having been first in great part severed, an incision was made along the middle line with a blunt-pointed bistoury, and the separation of the two halves was completed with the finger. Two écraseurs were then applied to the two halves, and worked simultaneously. When the tongue had been almost crushed through, a ligature was applied to the pedicle beyond the écraseur, and the separation on each side then completed by cutting. The enlarged gland was then removed through an incision in the skin beneath the lower edge of the jaw.—Nov. 24th: Nothing specially worthy of remark occurred after the operation; and the patient left the hospital well at this date.

The operation to which I have here drawn attention is one which is so much less difficult than many among those recommended, that I venture to think it will often be adopted by others, as it has been by myself, in cases which at first sight may seem unsuitable for any operation at all. I refer more particularly to cases in which lymphatic glands are diseased, and too extensively to admit of removal. It is true that no long period, if any, of complete immunity from pain and other trouble can be expected. But if we cannot completely remove the disease, it is of great importance to reduce its evils to a minimum; and in these cases the removal of the cancer from the mouth gets rid at all events of the most distressing of the patient's sufferings. Cases 6 and 8 are good examples in point. In the latter the lymphatic glandular enlargement was very considerable, even at the time of the operation; but the subsequent relief was great.

ON APHASIA, WITH LEFT HEMIPLEGIA.

BY J. HUGHLINGS JACKSON, M.D., F.R.S.,
PHYSICIAN TO THE LONDON HOSPITAL, AND TO THE NATIONAL HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

SINCE, in the vast majority of cases, affections of speech go with right hemiplegia, and since left hemiplegia is rarely so complicated, it is a matter of importance to inquire as to right- and left-handedness in all cases of affection of speech. It is particularly important with regard to the well-known hypothesis of Broca and Moxon. In the *Medical Times and Gazette*, August 25th, 1866, I suggested this inquiry, mentioning the case of a man who had defect of speech with left hemiplegia. This patient lamented that the paralysis was left-sided because he was "a left-handed man." He had had hemiplegia of the right side without any affection of speech. This matter had some time before been fully discussed by Broca. The subject of left-handedness has been both philosophically and practically considered by William Ogle and Pye-Smith. In nearly all cases I have seen in which affections of speech have occurred with left hemiplegia the patients have been left-handed. Of course, it is a significant thing that affections of speech *nearly always* go with right hemiplegia; but a fact of far greater significance is that disease in but one lateral half of the brain, be it right or left, can destroy speech. There is another fact of equal significance—viz., that lesion in but one half does not produce wordlessness. For when damage of one side of the brain destroys speech the patient remains able readily to understand what is said to him, at any rate on all matters simple to him before his illness. This is proof positive that the speechless man retains nervous arrangements for words. Lesion in one-half of the brain, left most often, produces speechlessness, but lesion in neither half produces entire wordlessness. The aphasic condition cannot, I think, be properly understood unless we bear this in mind. It has been said that cases of aphasia give clear proof that thought, and elaborate thought, is possible without words. But the completely aphasic person is not wordless, although he is speechless. It is not a theoretical statement, it is a matter of demonstration that the speechless man is not wordless. I have been speaking of ordinary cases. In some cases of vast lesion in the mid region of the left cerebral hemisphere we are unable to say that the patient does understand all we say to him.[1]

In this inquiry we ought to note the sort of hemiplegia the patient has. To the best of my observation, the more the leg and the less the arm suffers the slighter is the affection of speech. And sometimes when the leg suffers very much and the arm very little there is no defect of speech, or only very transitory defect. Again, I may say, that, as Hammond has pointed out, slight and transitory hemiplegia occurs most often with that kind of aphasia in which there is a copious utterance of words, with mistakes of one word for another, with round-about expressions, &c.

A case of loss of speech (the patient could only utter the words "come on to me" or "come on," and "yes" and "no"), with left hemiplegia, under my care in the London Hospital, is noted in the Hospital Reports (THE LANCET, March 17th, 1868), as an exception to the rule that the hemiplegia with aphasia is right. In the number of that journal, April 4th, 1868, appears a letter from me stating that the patient was left-handed, my friend, Dr. Prevost of Geneva, who saw the patient with me, having suggested the inquiry. No necropsy was obtained in this case. I may here give further remarks on the patient's left-handedness. Four of his six children—those by his first wife—were left-handed; the two by his second wife were not. It is proper to state, for what it is worth, that she said she always corrected her own two children when they used the left hand instead of the right. We may, however, assume that all mothers do so. The patient wrote with his right hand, but used the left for other things—for his knife when repairing boots, &c.

Sometimes a patient is said not to be left-handed because he writes, uses his dinner-knife, &c., with his right hand. This is an error. Left-handed children are not allowed to write with the left hand, nor to use the dinner-knife, spoon, &c., with that hand. A left-handed patient recently under my care, in reply to the remark that he wrote with his right hand, said that the reason was that his schoolmaster used to walk about the school with a short stick and would hit him on the knuckles when he (the patient) had his pen in the left hand. Left-handed soldiers are not permitted to use the left hand for the sword, although, perhaps, they may in fight. A left-handed compositor could not use his left hand for setting up types.

The following is an unpublished note, nearly as I took it down at the time, some years ago, of a case of partial aphasia, with left hemiplegia. It will be seen that an important part of a sailor's work was of necessity done by the right hand.

[1] I have suggested that the process of which speech is the end is preceded by an automatic reproduction of words. It has recently occurred to me to inquire whether the process of receiving speech of others may not also require a double service of words. It may be that whilst in an ordinary case of aphasia speech is impossible from disease in the left cerebral hemisphere, and ability to understand speech remains, there may for the latter purpose be a double process, starting in the right cerebral hemisphere and ending in the higher centres of the left—centres higher than those commonly believed to be the sole speech centres.

Thanks to the courtesy of my late friend, Dr. Harry Leach, I had the opportunity of investigating an interesting case of defect of speech, with left hemiplegia, in the Seamen's Hospital. At present the hemiplegia is very slight indeed; it amounts only to a little weakness of the arm, but it is clear that this side was considerably affected at the time when speech was lost. It will be observed that part of the history is given in the patient's aphasic language. Six months ago, when in the Calcutta river, during hot weather, the patient felt tired, and had no appetite. When one night at the wheel "could not when I see the compass tell the right thing." He remarked to a shipmate that he, the patient, had lost his speech. [Here the patient stopped in his account altogether; I urged him to go on.] "Said perhaps to-morrow night." He went to bed and "sleep for hours, and was awoke; when awake no speech. Captain came forrard." [Here I could not get to know what the captain had said; the patient's words were spoken in a low tone, and as if jumbled together.] "Was four or five or six days to be." [Then he stopped; I urged him to go on.] "There was a slate, and for three or four days, I suppose, and I thought I would try and my write and pen up, and could not do at all." I gathered from this that he tried to write. I said, "*Why* could you not write?" He replied that he did not know. He could not read at that time, although he could see. He did not know why. He was in bed one week. I asked him what the captain thought of him. "Captain said speech come a time, a little."

He could write his name readily, using his right hand. He could copy with perfect accuracy, and brought a slate with verses from the New Testament written on it. I told him to write the name of the place where he was taken ill. He wrote "Ca," and then stopped. I urged him to go on. He replied, "I can't," but in about half a minute he added "cuttir" to the "Ca." I asked the name of the place. He replied readily, "Calcutta." I next asked him to write the name of his ship. He wrote "*Thakote*," but told me the name was *Stanhope*. I then asked him to write the day of the week. He wrote "Sa," then "urday," and then "ey" (=Sautuey). I asked him to tell me the name of the day. He readily said "Saturday." Next I tried him at reading. He read quite correctly, but very slowly, word by word, like a schoolboy, but he made no mistakes. I urged him to read fast; *then* he made blunders—"virtue" for "virtue," "have" for "happily." But he stuck fast altogether very soon, and on resuming went on slowly and correctly. He wrote to dictation, with but few mistakes, and those possibly owing to defective education; but he wrote very slowly, and only word by word.

I asked him if he was left-handed. He said he was. I asked him how he knew he was. He said "Took a handful in my left." (I suppose he meant this for illustration's sake.) He always used to cut his food with his left hand. He added, of himself, that he used the needle (in mending sails) with his right hand. I asked him how this was if he was a *left*-handed man. He replied, "Whenever I come that, when I, I can't, cannot make myself." Here he stopped, and I urged him to go on and tell me why, if he were *left*-handed, he used the needle with his right hand. "Well, when I, when I do the thing, or any, any, any sort, the palm, you know they put it on the right hand." "Why?" I asked. "Because that's because why they've none in the ship—not eh, eh, palm for lab, left hand."

I gather from this and from his gestures that in using the needle he forced it through the sails by help of some leather apparatus, and that this apparatus would not fit the left hand, just as a glove for the right would not fit the left. I then remarked to him that he wrote with his right hand. He said, "Brought it to be learned with right." (Brought up to write with the right hand.)

I would remark here on the importance of noting slowness of speech and hesitation in estimating degree of aphasia. Slowness and hesitation are signs of impairment of speech. It is interesting to note that this patient wrote very slowly, and that he read worse when hurried. But the possibility that this patient was imperfectly educated renders these facts of less value. No doubt degree of education has much to do with the degree of writing power (expression by writing) in cases of aphasia. For high education in writing means that writing has become highly automatic.

There was some years ago under my care in the out-patients' room at the London Hospital a man, twenty-one years of age, who had defect of speech, inability to write and to read, who was hemiplegic of the left side. Yet there seemed to be circumstantial evidence that he was not left-handed. His father, his mother reported, had found great difficulty in getting him to use his left hand in caulking, in which the left hand has to be used. This man had had two attacks of convulsion, and it is possible that there was a double lesion. Of course without an autopsy it is impossible to be certain. Dr. Wadham (St. George's Hospital Reports, 1869) has recorded a case of left hemiplegia with aphasia. The following is from Bateman "On Aphasia:" "The subject of Dr. Wadham's case, a young man of eighteen, belonged to a left-handed family, as four of his brothers as well as himself were left-handed. This case having terminated fatally, there was found to be almost an entire absence of the island of Reil on the *right* side, its place being occupied by a large cavity containing a little fluid and a small amount of broken-down brain-matter; the *left* hemisphere was perfectly healthy." This case is one of extreme value, as there was an autopsy.

ON MEDICAL CERTIFICATES OF INSANITY.[1]

By T. N. BRUSHFIELD, M.D.,
MEDICAL SUPERINTENDENT, BROOKWOOD ASYLUM, SURREY.

I HAVE been induced to write a paper on the subject of Medical Certificates of Insanity, and for two distinct reasons: first, to afford those medical practitioners who have not directed much time to the study of insanity some practical hints as to the entries to be made in them, and which are wanting in the ordinary text-books;[2] secondly, to point out some imperfections in the present statutory form of certificate, and to suggest some additions and alterations, so as to render it more comprehensive, satisfactory, and complete.

I know of no position in which a medical man is placed in a greater state of embarrassment than when, perhaps without having had any previous practical acquaintance with the subject, he is suddenly called upon to treat or to advise upon the treatment of his first case of insanity. The issues are so important, involving as they do the welfare of the patient and the happiness of his family, that when he asks himself the momentous question as to whether it be a case for home treatment or for removal to an asylum, the professional man can then realise the serious responsibility attached to the opinion he will have to give to the distressed relatives; this can only serve to intensify his own anxiety. When he *has* had some previous experience of the nature and treatment of mental diseases, it will be a comparatively easy task for him to arrive at some definite opinion as to the plan to be adopted in the particular case, as well as to give valid reasons to the relatives for his decision. I may remark that, from his previous knowledge of the patient, the regular family practitioner can distinguish and appreciate any change in the demeanour, habits, and conversation of the person to be examined, as compared with the previous condition, far better than any stranger who may be called in. The medical man having decided to recommend the immediate removal of the patient to an asylum, and the relatives having consented to this, the law requires that prior to his admission there, certain statutory forms be filled up, the most important of which is the medical certificate of the patient's insanity. In the case of a private patient two such certificates are needed; in that of a pauper only one. There is no difficulty in filling up the more clerical portion of these certificates, as the printed forms always contain copious marginal explanations. The necessary form for a private patient may always be obtained from asylums receiving that class of inmates. In the case of a pauper it is the duty of the relieving officer to supply one.

For practical purposes we may divide the certificate into two distinct portions, the *statutory* and the *medical*. Let me here state that I purpose throughout my paper giving illustrative excerpts from certificates that have come under

[1] A *précis* of this paper was read at a meeting of the South-Eastern Branch (West Surrey district) of the British Medical Association, held at Farnham on March 25th, 1880.

[2] The work containing the best remarks upon the subject is the small but valuable one by Dr. Millar, entitled Hints on Insanity, and which has reached its second edition. As far as I know, the only paper on this matter is Dr. Buckwill's admirable but too short one published in the Asylum Journal, vol. vii., p. 79 et seq.

my own personal observation at the Brookwood County Asylum.

The more strictly *statutory* portion comprises all the first or introductory portion of the form, and there are several important particulars for the certifier to bear in mind respecting it.

The first one to notice is that in the case of a private patient the medical man must "separately from any other medical practitioner" (16 and 17 Vict., cap. 96, ss. 4 and 10) examine the patient and form an independent opinion as to the existence of insanity. The law is so jealous—as it should be—of the slightest collusion between the two certifiers, that too much caution cannot be exercised in rigidly carrying out the statutory requirement. Even with respect to the two certificates being on the same paper, the judge in the recent case of Nowell v. Williams remarked: "Anything more calculated to lead to the law being broken I cannot imagine." The medical men should not be together in the same room during the examination of the patient; they should not see each other's certificates before writing their own (hence the reason why they should not be written on the same paper), or hold any converse about the case until each had finished his own certificate. A breach of any of these points might lead to the document being declared invalid in a court of law, and cause the practitioner much trouble and expense.

The second is to be scrupulously careful in filling up the various particulars as to medical qualifications, when and where the patient was examined, &c. Some years since Mr. Justice Coleridge declared a medical certificate to be invalid as it omitted to mention the name and number of the street where the patient was interviewed. It is a matter of general complaint amongst asylum superintendents as to the irregular manner in which the statutory portion of the certificate is filled up. The marginal explanatory notes are so plain that there is really no excuse for blunders of omission or commission. I have counted no less than five errors of this kind in one form. One medical man testified to have seen the patient in November instead of in February. Another, that he had examined the patient on a date five days *subsequent* to that of his certificate. All errors of this class might easily be avoided by the exercise of a little common attention on the part of the medical man, and so save a great deal of unnecessary trouble.

The third is for him to bear in mind that it is immaterial whether he uses the term "lunatic" or "a person of unsound mind," either being equally valid. By the statute (16 and 17 Vict., cap. 97, c. 132), the term "lunatic" shall mean and include every person being of "unsound mind, and every person being an idiot." There is no occasion to qualify either term in any way, such as by calling the patient a "confirmed lunatic."

The fourth point for him to notice is that, after stating the patient to be a lunatic (or person of unsound mind), the statutory wording runs thus: "And a proper person to be taken charge of and detained under care and treatment." This, it will be noticed, contains no reference whatever to any dangerous proclivities on the part of the patient as constituting the basis of asylum detention. The existence of such a limitation would prevent a large number from being sent away from home, but who certainly require asylum care and treatment equally with those who are directly dangerous to themselves or others.[3] I wish to direct especial attention to this, as the relatives of private patients sometimes urge the non-existence of dangerous symptoms as a reason against removal to an asylum; and in the case of paupers I have on several occasions known magistrates refuse to sign the order of admission unless satisfied the patient was dangerous. During the present year a case of this kind was brought under my notice, when the magistrate declined to sign the order unless the medical man certified to the patient being in this condition. This he did in the body of his certificate thus: "I believe him to be a dangerous lunatic"—a statement that was not of the slightest value, but, on the contrary, was irrelevant. The law requires the testimony as to whether the patient be suicidal or dangerous to others to be contained in the statement signed by the relieving officer in the case of a pauper, and by the relative in that of a private patient.

The fifth is for him distinctly to understand that the patient must be admitted into the asylum within seven clear days of his interview with him; not necessarily within that period of the date on which the certificate was signed, as that not unfrequently takes place some days after the examination is made. It is of especial importance for the medical man to inform the relatives of this fact in the case of a private patient, and so prevent the possibility of the patient's reception into the asylum being refused owing to illegality of the certificate from lapse of date.

A male patient was brought for admission into the Brookwood Asylum on April 20th, 1877. The certificate was dated April 14th, and testified that the medical man had seen the patient on March 21st, on which last-named date the patient "was a person of unsound mind." I need scarcely say admission was refused.

In addition to the foregoing particulars several other points also require attention—e.g., the certifying practitioner must be registered, and must be in actual practice. The patient must not be examined in an asylum or licensed house, where it is intended for him to remain. The Commissioners in Lunacy called attention to the following points in a circular issued by them a few years since:—"Certificates signed, or founded on medical examinations made elsewhere than in England or Wales [the extent of the Commissioners' jurisdiction] are not accepted as a valid authority for the detention of a patient within that jurisdiction. Every certificate should be an independent and complete document, and no reference should be made therein to another."

I now pass on to consider the essential part of the certificate—the medical; and which is required to contain a detailed statement of the symptoms upon which the medical practitioner has formed his opinion as to the patient's insanity, &c. Formerly it was not obligatory for medical men to state "the grounds" (the statutory word for symptoms) upon which this opinion was based. In the case of a private patient it was necessary to procure two medical certificates, to the effect that A. B. was "of unsound mind, and a proper person to be confined"; one certificate only being required for a pauper lunatic, who was certified to be "of unsound mind," but whether "a proper person to be confined," or not, was not alluded to. One of the greatest modern improvements in the lunacy law, was that contained in the Acts 16 and 17 Vict., capp. 96 and 97, which annulled the old form of certificates, and required that every medical man should state his reasons in detail for declaring any patient to be insane, and under the two following headings:—1st. Facts indicating insanity observed by myself. 2nd. Other facts (if any) indicating insanity communicated to me by others; the evidence under the first being of a *personal*, and under the second of a *hearsay* character.

Before the medical man attempts to commit his statements to paper, it would be well for him to pay due attention to the following points:—

1. He should thoroughly understand that he may have to defend all his "facts" in a court of law, and this alone should make him exceedingly cautious in all his written statements.

2. To avoid all hearsay evidence under the heading of facts observed by himself. The statement "he has not been to bed for eight nights, nor has he removed his clothes during that time," was included under the first heading of a certificate, and yet it could scarcely have fallen under the direct observation of the certifier. It was evidently derived from the information of others, and ought to have been relegated to the second heading, together with the name of the informant. In the position it occupied it was irrelevant.

3. To remember that all his personal facts must have been observed on the day of examination. Medical men who have been in attendance for some length of time upon the patient are frequently apt to mention symptoms that have been noted on some previous day, and which may have passed away, or were not discoverable on the certified day of examination. Here is an example:—"On the 9th instant" (the patient having been examined on the 14th)—"she was under the impression that the food she was eating or had eaten was not human food, but something very bad, for which there was a necessity for her to eat on account of something she had done." Had this been the only proof of

[3] In the remarkable case of Nottidge v. Ripley, the judge appeared to be of opinion that no person ought to be confined in an asylum unless he was dangerous to himself or others. The Commissioners in Lunacy, in a letter to the Lord Chancellor commenting upon this opinion, said: "The object of these Acts is not, as your Lordship is aware, so much to confine lunatics as to restore to a healthy state of mind such of them as are curable, and to afford comfort and protection to the rest." Moreover, the difficulty of ascertaining whether one who is insane be dangerous or not is exceedingly great, and in some cases can only be determined after minute observation for a considerable time.

Digitized by Google

insanity, the certificate would have been illegal. Other delusions were, however, mentioned in detail, and made the document valid. Here is another: "She for some time has been in a very strange mental condition, and has been under many delusions." This was followed by a statement of existing delusions.

Medical men are frequently placed in a most awkward position by being called upon to certify in cases where after a thorough examination they are unable to give a written certificate, owing to the absence of decided symptoms of insanity, or if any be present they are of a weak kind. This occasionally happens in cases of epileptic mania with homicidal propensities, where perhaps the outbreak of violence has ceased prior to the arrival of the medical practitioner, who finds the only observable symptoms are those of epilepsy alone. Also in remittent and in recurrent mania, during the intervals of the attack, when in the former the symptoms may be undecided in character, and in the latter altogether absent. Again, in suicidal mania, he may have been called in soon after a deliberate attempt at self-destruction, the mental symptoms being in abeyance. A similar temporary absence of symptoms may occur in many other forms of insanity.

The medical man may know the patient to be insane, but at the same time can adduce no legal proof of it from the facts observed by himself. On the other hand, the relatives being convinced of the existence of insanity, may accordingly urge the medical man to certify, so that all the onus and responsibility of the case rest upon him. Under such circumstances what is he to do? The answer is very simple:—1st. Under the Statute 16 and 17 Vict., cap. 19, sec. 75, he cannot write a valid certificate of the patient's insanity unless he can testify to it by symptoms observed by himself on the day the examination took place. 2nd. His proper duty then is to advise the relatives as to proper precautions being taken to prevent the patient doing harm to himself or others; and to send for him immediately any additional and decided insane symptoms become apparent.

4. He should report the facts observed by others, under the second heading, as carefully as those under the first. This is, however, rarely done, and some certifiers omit making any entries of hearsay information. The testimony of others frequently corroborates that given by the medical man. It is also of especial service in recording acts of violence, attempts at suicide, the frequency and character of epileptic attacks, the extravagances of general paralysis, depressed habits and propensities, overt acts of insanity generally, and a variety of important matters not likely to fall under the direct personal knowledge of the certifier. It therefore not only frequently reports the most important symptoms of the patient's malady, but is also a good medium for conveying to the asylum medical officers much valuable information of the history of the case, which otherwise they might not be able to obtain. The following is a good illustrative example:—1. *Facts personal.* "He lies in bed in an apathetic state, and with a vacant expression, and answers questions in an inconsequent manner. He has been under medical treatment during the last year with no improvement in his condition, and there seems to be no chance of recovery while he remains at home; he evidently requires the regimen and moral treatment of an asylum." It will be observed that more than one-half of this portion of the certificate is irrelevant and unnecessary. 2. *Facts hearsay.* "His wife informs me that he has been unemployed during the last fourteen months, that he is quite indifferent as to the wants of his family, that he practises masturbation to a great extent even before his children, and that a month since he nearly strangled one of his children for touching the cat which he was nursing, and that she is afraid to leave him alone with them." Scarcely an indication of the nature of the disease is contained in the first portion, whilst the second is a good description of some of the principal symptoms of fatuity passing into dementia caused by prolonged masturbation.

5. He must ever bear in mind that no matter how strongly the facts observed by others may testify to the insanity, the certificate is invalid if the medical man is unable from his own personal observation to adduce such facts as will in themselves show the patient to be insane. Some time since, on returning a weak certificate to be amended, the medical man replied, "I cannot furnish you with any other facts as proofs of the woman's insanity, probably some of her relatives can if you desire them."

6. He should not be satisfied with the record of one decided symptom of insanity (such as a well-marked delusion) to the exclusion of all others. On the contrary, he should examine the patient thoroughly, and, at the least, report all the principal symptoms. A certificate which depends upon proof of insanity by the statement of a single delusion would, in an important law case, run a possible chance of being disputed as to its tenour and correctness.

7. He should take care to state all the leading symptoms—e.g., dominant delusions—and as tersely as possible, consistent with their being properly described and expressed. The omission of all mention of the principal delusion is of frequent occurrence. Here is an example:—*Facts personal.* "Talks in a very excited manner. Says he has an innumerable number of complaints. Keeps a knife by his side, with which he sometimes threatens his wife, and when asked why he does it replies that he thinks it his duty to kill her. Very restless and sleepless at night, and at times appears as if he were in a semi-conscious state." The important part in this relates to the knife, and the threats used in connexion with it. The certifier could scarcely have had a personal knowledge of these matters. If this be the correct surmise, he should have stated, "*I am informed* he keeps a knife, &c." But even if the whole account were true it was not inconsistent with sanity. Some sane but brutal husbands have been known to do the same kind of thing. The omission of the motive for wishing to kill his wife was the weak point in the certificate, and this was at once supplied by the patient himself at the time of his admission, who, being examined by the asylum medical officer, owned that he heard (imaginary) voices speaking to him during the night, and which prevented him from sleeping, and that they sometimes told him to kill himself. The certificate was returned to be amended, when the medical man added the following:—"Fancies he hears voices at night telling him to murder his wife, also that his property is increasing, and that he will come into it shortly." A good certificate need not, as a rule, be a long one. When characterised by length and diffuseness it too often contains inconsistencies, contradictions, and weak points. The longest certificate I ever had contained 311 words of the facts observed by the medical man alone, and might have been included in these short lines: "Entertains the delusion that almost every person with whom he comes in contact is in a conspiracy against him." There is no need to write out particulars at length, which simply serve to show incoherent language. Minute details to demonstrate defects of memory are equally unnecessary. The following is an extract from the certificate of a case of epileptic dementia: "Labouring somewhat under mental confusion and imbecility, as evidenced by his inability to tell me at this time the number of days in a week, of the present year, of the name of the present month, &c." "Memory defective" would have correctly expressed all the latter portion of this statement. The "mental confusion and imbecility" were entirely distinct symptoms, and were really expressive of the dulness, obtuseness, and gradual decay of the intellect so common in these cases. A certificate, if unduly short, errs in the opposite direction to a long one. The following is a good example: "Facts 1. Violent, incoherent, destroys his clothing. 2. None." The case was one of mania with general paralysis, and exhibited all the characteristic delusions of the latter disease. The term "incoherent" was scarcely applicable to his condition, and the principal symptoms (delusions), proving the patient to be insane, were not mentioned.

8. He should remember that any comment upon, or explanation of, the symptoms, is not required. Such a statement as "a condition doubtless connected with the epileptic seizures to which he is subject," is quite unnecessary. "This patient, admitted recently (into the workhouse), is suffering under confirmed melancholia"; "appears to suffer from melancholia"; appeared in two certificates, the certifier appearing to forget that these assertions simply amounted to stating the patients were insane, whereas the facts or symptoms upon which they grounded these opinions were demanded by the statute. Such a sentence as "I am of opinion this person is a dangerous lunatic" is not of the slightest value, but the facts upon which the medical man based this opinion would have materially enhanced the value of his testimony. All such expressions in no way add to the validity of a certificate, and should be scrupulously avoided.

9. He should avoid making any statement under the first heading of the certificate that is not legitimately included

Digitized by Google

under that of "*Facts* indicating insanity," and "as observed by *himself*." Under this title one medical man stated as a personal fact: "called me a fool." Irrelevant statements cannot strengthen a certificate, but may assist in making it invalid. In a court of law, where the reception of any such irrelevant matter would be prejudicial to the interest of his client, I question very much whether the counsel engaged would not object to the reception of any such evidence, as being contrary to the requirements of the statute, and with every probability of his objection being entertained. Undoubtedly much of this kind of information should be reported to the asylum medical officer, but unfortunately the present form of certificate is defective in containing no place or heading for its insertion. When, although important, it is unable to be included under the second heading, it is always the better plan to let it form the subject of a letter to the asylum medical officer, when at the same time many medical points —such as any history of syphilis—may be noted, and which could not always be stated in any form of certificate. It rarely happens that an entire certificate is irrelevant; the following, however, is rather a remarkable example of one, and contains all the "facts" recorded by the certifier:—"In the summer he repeatedly was in the search of adders, would endeavour to play with them, so subjecting himself to be stung, which he has been on one occasion very severely; would kill them and eat their hearts. On my asking the reason, he would say if he ate a number they would cure the epileptic fits which he has suffered from for eleven years. On several occasions he has threatened to take the life of his smaller brothers and sisters." This statement contains no symptom of insanity—a belief in the curative powers of adder fat, &c., is prevalent amongst the squatters resident on the common lands in the Bagshot Sands district; and amongst the lower orders generally an ignorant belief in the efficacy of a large number of very unorthodox remedies for epilepsy is very common. The threats of violence were not inconsistent with perfect sanity. The greater portion of it consists of hearsay evidence, and none of it apparently refers to the day of examination. The certificate was returned for correction, when the medical man added the following:—"He is sullen, morose, and dejected. Answers questions in an incoherent manner, and appears quite indifferent as to his fate."

10. When called to a case of reported insanity, he must not too readily take it for granted that the patient is insane, and especially must this be borne in mind if he be a stranger to the family, and therefore probably unacquainted with the manner and habits of the person he is about to examine. It behoves him to be exceedingly particular, more especially in any doubtful case, in investigating and thoroughly satisfying himself of the nature of the symptoms. Especial care must be taken when the so-called delusion is single. Any statements that are asserted to be delusions, and yet which *might* be true, need the most searching inquiry. For instance, the following single one appeared in a certificate:—"She has a delusion that some one pays for her retention in the workhouse." An assertion that was quite likely to be true, but if even a delusion, it was a very weak one. The most difficult case for a medical man to deal with, and the one most likely to be brought under his notice, is that where the single delusion is reported to be that of jealousy on the part of the husband or wife, the subject of which strenuously asserts it to be well-grounded. The possibility of the latter, and the probability as to motive, should be well considered by the medical man before he pronounces any opinion on the case. If there were an entire absence of any other symptoms of insanity, I should for my own part refuse to sign a certificate Febrile delirium is occasionally mistaken for insanity. The acceptation of truths as delusions does occasionally take place. The certificate of a patient recently brought to the Brookwood Asylum commences thus:—"He has various delusions, all bearing on engineering projects. His first and chief project is to carry a triple tunnel under the English Channel from England to France." At first sight this has all the appearance of a delusion, but as a carefully-considered scheme I have cause to believe it was a reality. The man had been an engineer, and had conceived and worked out on paper a plan for such a tunnel, which had met with the approval of many leading men of the day (the papers proving this are in my possession). There was no reason to doubt the man's insanity, the symptoms of which appeared in the certificate. He had overworked his brain, had broken down, and becoming pauperised was sent to a county asylum. Now if this single symptom had been depended upon to prove him insane, and the question of his sanity or insanity had subsequently been inquired into by a court of law, no doubt the medical certifier would have got into serious trouble.

11. He should take into consideration the existence of blindness, deafness, partial paralysis, malformation, defects in speech, loss of teeth, infirmities of temper, peculiarities of gesture, eccentricities of conduct, or in the mode of speech, &c., many of which cause the person to be examined to be somewhat awkward and ungainly in speech and manner, especially if associated with any nervousness. These states are not unfrequently jotted down as proofs of insanity. In one certificate I received was the sentence "a vacant expression" as one of the facts indicating insanity, and yet it appeared to be entirely owing to deafness. Deaf persons, even when sane, are frequently listless and vacant, and, moreover, are apt to be suspicious from a belief in thinking they are always being talked about.

12. He should well consider that the element of any *change* in the habits, conversation, affections, disposition, dress, residence, choice of companions, &c., is of the greatest importance to notice in the certificate. In themselves all the varieties of demeanour and speech may be perfectly natural to the individual, and are therefore perfectly consistent with sanity. If, on the contrary, any of these show a marked change (often a complete antithesis) to his previous condition, they become valuable evidence of insanity. The lower classes of society may be considered as perfectly sane, even when from the force of habit they employ the most coarse and objectionable language; but the same low-life and often obscene utterances emanating from the mouth of a lady, and presenting a strong contrast to her mode and previous style of conversation, would, especially when taken in connexion with other symptoms, be a strong indication of mental impairment. Change in the style of language is well reported in the following extract from a certificate (the patient was a well-educated gardener):—2. *Facts hearsay.* "His wife says ..... that he is constantly using the most violent and obscene language before her and the children, which has never before been his habit."

13. He should be careful to use proper terms to express his meaning. In the two sentences, "incoherence of speech and manner," and "her manner wild and incoherent," the words "incoherence" and "incoherent" used with respect to "manner" are inapplicable. Again, in the sentence "all her conversation is illusive," the term "illusive" was used in a sense that scarcely agreed with the subsequent context. He should avoid as much as possible the use of single words to express the patient's conversation or demeanour, such, for instance, as "irrelevant" and "vacancy."

Above all, when he has finished writing his certificate, he should be careful to reperuse it. If this had been done after the certifier had written, "has an expression of deep dejection and an unsmiling countenance," it is probable he would have struck out the latter sentence as being superfluous.

(To be continued.)

NOTES OF A CASE OF HYPERPYREXIA.[1]

BY G. H. PHILIPSON, M.A., M.D. CANTAB., F.R.C.P.L.,
SENIOR PHYSICIAN TO THE NEWCASTLE-UPON-TYNE INFIRMARY; PROFESSOR OF MEDICINE IN THE UNIVERSITY OF DURHAM.

A. B——, aged twenty-three, unmarried, a domestic servant, was admitted into the Newcastle-upon-Tyne Infirmary, under my care, on July 4th, 1879. From information obtained from her mother, the patient's life during the past three years had been one of difficulty and hardship. In former years the patient's parents had been in good circumstances, but through misfortune their children had been obliged to enter service to gain their livelihood. Three years ago the patient had suffered from an attack of rheumatic fever, and then her medical attendant had been obliged to have recourse to narcotic remedies, but had strictly enjoined that she had not to take more than was absolutely necessary to relieve her suffering. Contrary,

[1] A paper read at the Northumberland and Durham Medical Society.

Digitized by Google

however, to his injunctions, she had taken them in large quantities, and suffered in health in consequence thereof. She also habitually would drink spirits of camphor, eau de Cologne, or anything spirituous in nature. She obtained large quantities of chlorodyne and other narcotic preparations unknown to her parents. She could not remain easy for more than half an hour without taking something stimulating or sedative in nature. She pawned silver articles and linen goods, and even her own clothes, to obtain chlorodyne. She sometimes would lie for hours in a deep sleep, and then would become frenzied, threatening to make an end of herself. If she was not able to obtain chlorodyne or some other narcotic or stimulant, she became very depressed. According to her own version, she took these substances for the purpose of relieving the severe pain from which she suffered. She admitted that she had taken as much as five teaspoonfuls of Collis Browne's chlorodyne at one time.

In March, 1877, she was three weeks confined to bed, with a severe pain in her left side, the severity of which, upon several occasions, produced fainting. The pain became more severe, especially after movement or exertion, and in order to obtain relief she resorted to a mixture of ether, ammonia, and opium, which she was in the habit of taking, and without which she said she could not exist. Her sight at this time would become dim, and for days she was almost blind. Her medical attendant becoming alarmed lest any hurtful result might arise from the careless self-administration of these uncertain medicines, forbade the chemist to supply her with them. However, it was discovered that subsequently she had procured the same articles from other chemists.

The patient was a young woman of medium stature, stout and of pale sallow complexion. Her countenance was dull and heavy; she was inert, easily excited, and highly sensitive. She complained of great pain in the chest and back, which was greatly intensified when the cuticular surface was touched. The pain was more especially associated with the intercostal muscles, was constant and very severe, and was worse at night and in the early morning. In the middle of the sternal region, in the left axilla and at the left side of the vertebral column, the tenderness was extreme. There was general hyperæsthesia of the surface, but the sensitiveness was most marked over the back and especially the left side. The skin generally was hot and dry; during the night, and at times during the day, she sweated profusely; the sweat was very sour and disagreeable in odour, and was strongly acid in reaction. She complained of great thirst, the tongue was thickly coated, micturition was difficult, and sometimes for a whole day no urine was voided. The urine was very dark, contained a copious sediment composed of urates and phosphates; its reaction was strongly acid, specific gravity 1030, and contained neither albumen nor sugar. The bowels were constipated. The catamenia had been absent for four months. The heart-sounds, base and apex, were sharp, but were without murmur; no friction, pericarditic or pleuritic, or other adventitious sound, was heard upon auscultation. The pulse was 84, and the respirations were 18 in the minute.

The case was regarded as one of hysteria, associated with amenorrhœa and intercostal neuralgia. She was placed in bed between blankets, and was ordered the milk diet, consisting of three pints of milk and boiled rice, with two bottles of potash-water, each day. She was also prescribed the compound iron and aloes mixture, three times each day.

During the first few days after her admission, there was not anything particular to note concerning her state, with the exception of the temperature, which became abnormally high. On the evening of July 7th it was 101° F., and on the evening of the 9th it became 112°. The following morning the temperature was 112°, and on the evening of the 11th it was again 101°. For the next three days the temperature remained between 100° and 103°. On the evening of the 16th the temperature again rose to 111°, and on the morning of the 18th it fell to 100°, and on the evening of the same day it rose to 112°. Three days after her admission, on account of the very high temperature and of the increased severity of the pain, Dr. J. D. Dixon, the senior house-surgeon, deemed it expedient to substitute for the iron and aloes mixture, twenty grains of the salicylate of soda in an ounce of water every four hours.

Notwithstanding the continuation of the salicylate of soda, the pain became so intense that it was decided to administer morphia hypodermically. At first one-quarter of a grain of the acetate of morphia was employed, by which she was much eased. After repetition, however, the effect was less marked, yet she was always most solicitous for the administration, and became much excited if it was postponed, a course which was considered expedient.

On July 24th the temperature in the left axilla was 117°, the highest recorded. On this day, in the right axilla, the temperature was 110°, and in the mouth 102°. On July 28th the temperature in the left axilla was again 117°, whereas in the right axilla it was 114°, and in the mouth 112°. On July 29th the temperature in the right axilla was 115°, the highest recorded in this situation, whereas in the left axilla it was 110°, and in the mouth 116°, the highest recorded in this situation.

Respecting the precautions taken as to the thermometric observations, it may be stated that the thermometers were placed and removed by the clinical clerk, and often under the direct supervision of the senior house-surgeon. Further, that on account of the excessively high temperature three thermometers of greater range than usual were specially obtained from Brady and Martin of Newcastle-upon-Tyne, and employed. These three thermometers were fixed at the same time, one being placed in the mouth and one in each of the axillæ. The temperatures in the evening were always taken previous to the administration of the hypodermic injection. During the time the thermometers were in position a nurse was placed at the patient's bedside, and was instructed to watch carefully for, and to prevent any, movement of the arms of the patient. Occasionally the patient was sullen and obstinate, and it was impossible to persuade her to allow the temperature to be taken.

On July 26th the salicylate of soda was omitted, and she was prescribed ten grains of the sulphate of quinine, with diluted sulphuric acid and water, three times each day.

At this time the sour smell of the perspiration became more intense, the hands were unsteady, and the skin commenced to peel off the fingers. On the surface of the trunk a roseolous eruption was also noticed. Her lower extremities were cold and she had shiverings. She also complained of severe pain in the head and face. For several nights she was very violent, and caused much disturbance in the ward.

As she continued to complain much of the pain in her head and face, on July 28th four decayed molar teeth were extracted. During their extraction she remained perfectly quiet. Shortly afterwards she said, "No one knows what a woman can do when she is determined," and then she fainted.

During the remaining days of her stay in the hospital she became exceedingly troublesome, and gave rise to much discomfort to the other patients, so much so that it was necessary for her mother to be sent for, and to be requested to remove her from the infirmary. She threatened to make away with herself, and required constant and most careful watching. On the evening preceding her departure the temperature was 98°, while five days before it had been 117°.

The temperature of the atmosphere during the whole time was always between 50° and 60°.

About the middle of September, 1879, the patient returned to the infirmary to visit a friend in the female ward. From the nurse's account, she appeared to be in good health, and looked well.

Remarks.—As has been recounted, upon admission the diagnosis was entered as hysteria, associated with amenorrhœa and intercostal neuralgia, and the sequence of events shows that the view taken was correct. The treatment was ordered accordingly. Subsequently, however, when the excessively high temperature was registered, the acuteness and the severity of the suffering indicated the propriety of the administration of remedies antipyrexial in nature; but, as was clearly manifested, without any distinctive influence. The most important point of interest unquestionably was the excessively high temperature. The highest temperature registered was 117°, 19° above the normal temperature of health. Occasionally cases of very high temperature have been recorded. Of such, excluding those the result of spinal injury, or after surgical operation, the following may be specified.

Wunderlich[1] "refers to a case, in a girl aged eighteen, who was often attacked with partial hyperæmias, urticoid eruptions, local sweatings, and very changeable and varied symptoms in different internal organs. Besides this, at other times than the local hyperæmias of the skin, she exhibited all over the surface of the body, from 1° to 1½° C.

[1] Medical Thermometry, p. 166.

Digitized by Google

(= 36° to 9° Fahr.) higher temperature than in the vagina, in the right axilla, as well as in the right groin, there was a persistently higher temperature than in the left, the difference being sometimes as much as 1° C. (= 2·7° F.) The highest temperature in this case was 103·1° Fahr. This very remarkable behaviour of the temperature, which lasted almost a year, could scarcely mean anything else but a disturbance of the vaso-motor nervous system, which, whilst it affected both sides, affected the right much more than it did the left."

Dr. Graham Steel[3] of Manchester has recounted a case that was under his care in the Manchester Royal Infirmary, in a female, aged twenty, suffering from hysteria, in whom the temperature was over 116·4°.

Dr. Horatio Donkin,[4] of the Westminster Hospital, reported that, in a female nurse, aged nineteen, during an attack of enteric fever, the temperature was over 111°.

The other points of interest, in reviewing the case under consideration, would appear to be the non-persistent character of the hyperpyrexial condition, its want of uniformity over the surface of the body, and the slight prejudicial influence of the condition upon the patient.

The non-persistent character of the hyperpyrexial condition was very remarkable, and would appear to be of significant importance in estimating the amount of actual danger to the sufferer. Often the exaltation of temperature was of very short duration; a second observation taken very shortly after the registration of a high degree might again be high, or, on the contrary, be of a lower degree, or even be the normal temperature of 98°. Respecting the want of uniformity of the temperature over the surface of the body, it was no unusual circumstance for the difference to amount to several degrees. As an illustration of this anomaly the following instance of the state may be referred to. On the 24th of July the temperature in the left axilla was 117°, that in the right axilla was 110°, and that in the mouth was 102°. This non-correspondence was no unusual circumstance. It was also distinctly associated with a corresponding difference in the hyperæsthesia. The exaltation of sensitiveness was generally most marked on the left side of the spine, the left side of the thorax, and the left arm. This want of uniformity of the temperature, conjoined with a difference in the hyperæsthesia, may be inferred to be another indication that the individual was in no imminent danger.

Regarding the apparently slight prejudicial influence of the high temperature upon the state of the patient, it is to be remembered that while the temperature was so increased as to be considered almost incompatible with life, and while she was reeking in perspiration, her mind was unclouded, and she answered questions quite coherently, the only alteration in her physical condition being that of peevishness and waywardness, a statement fittingly described as "hysterical." Another point worthy of allusion is that the pulse and the respiration never altered, the ratio being 4·5 to 1, corresponding with the normal pulse-respiration ratio. This is of diagnostic import, for, in the ordinary pyrexial condition, in which the rise of temperature is persistent, the pulse and the respiration also increase synchronously.

The conclusion, therefore, in the contemplation of the case, is, that in the absence of pericarditis, endocarditis, or other inflammation, the hyperpyrexial condition was the consequence of an influence derived from the vaso-motor nervous system, or a neurosis, and that the many and characteristic manifestations of hysterical state very fittingly indicate that the designation of hysterical neurosis is the most appropriate epithet to apply to the case.

For the very complete and extended thermometric record I am indebted to Dr. J. D. Dixon, the senior house-surgeon, and Mr. W. H. Davis, the clinical clerk. For the notes of the case I have further to express my obligation to Mr. W. H. Davis.

CASE OF PERFORATING ULCER OF THE STOMACH; DURATION OF ACUTE ATTACK, THIRTY HOURS; AUTOPSY EIGHTEEN HOURS AFTER DEATH.

By JOHN LACEY, M.R.C.S. Eng., &c.

THE following case may be of interest to the profession. The patient, up to the time of the attack, was exceptionally healthy and active.

[3] THE LANCET, 1879, p. 271. [4] Ibid., 1878, p. 678.

The body was that of a young woman about twenty-two years of age, well-nourished. There was no sign of decomposition; the colour of the skin all over the body was of a light olive. On the body being opened in the usual manner by a longitudinal incision down the median line from the ensiform cartilage to the pubis, a layer of fat was observed about one inch and a half thick, of a yellow colour, darker than usual. On opening the cavity of the abdomen a rush of a considerable quantity of air took place, and on the intestines being exposed the presence of acute inflammation could be noticed in the pinky colour and almost universal glueing together of the intestines with coagulable lymph, with here and there a patch of redness, and about three pints of grumous serous fluid of a brownish dirty red. The serous covering of the liver was dull-looking and opaque, and looked as if macerated by the fluid; some of which, no doubt, had escaped from the stomach; on looking at which, but without removing it, a brownish-red spot about the size of a sixpence was observed on the front wall of the viscus, a little to the left of the centre. The stomach was carefully removed, and the opening of the ulcer was examined from the inside; it had the appearance of being of rather long-standing, as there was much thickening of the wall of the organ in the neighbourhood of the ulcer. There were also two other ulcers, rather larger than the one that had perforated the stomach, on the posterior wall, about the same level as the perforation; they were not so deep as the ulcer in the front, but so little tissue remained that when very lightly felt the wall gave way. The gastric inner surface appeared otherwise healthy. There was observed on the outer surface at the lower part of the stomach a wrinkle, as if the organ was forming the usual hour-glass appearance or contraction that takes place in this disease. The uterus was pale and rather contracted; the ovaries dark-coloured and nodulated, and on cutting into them several cysts were divided, which spurted forth a light-coloured fluid. In the right one a yellowish cavity was observed, not so large as a corpus luteum, but evidently the product of some inflammatory action. The mesenteric glands were also somewhat enlarged. The rest of the body appeared healthy.

There had been no marked symptoms of disease in the patient before, the only observable one being the olive colour of the skin, described above, which had existed for about two months, with loss of appetite, and a slight complaint of pain after food.

I think the above fully exemplifies the insidious nature of the disease.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

RICHMOND HOSPITAL.

CASE OF INGUINAL HERNIA WITH BONE IN THE INTESTINE; DEATH; REMARKS.

(Under the care of Dr. A. ROBERTS LAW.)

A. B——, aged seventy-four, applied at noon on Monday, Sept. 15th, 1879, for admission to the hospital, having, he said, walked about two miles in great pain. He gave the following history. On the previous Saturday (13th) night he went to bed feeling well, and with no particular swelling; when he rose on Sunday morning he felt ill, and noticed a tumour in his left groin. He believed he had been ruptured for three years, because occasionally a small tumour came in his groin, which caused him no pain, and always disappeared without assistance. He had never worn a truss nor had advice. He was unable to eat anything all Sunday (14th), and had frequent calls to stool, but was able to pass only one or two small lumps of fæces, and no flatus. He felt sick, but neither retched nor vomited. Thinking the

Digitized by Google

tumour would disappear as usual, he sought no help until the next morning (the day of admission), when he went to a medical man, who told him he had a rupture, and endeavoured for ten minutes to return it. Failing in this, the medical man advised him to apply at the hospital.

On admission, a tense elongated tumour, somewhat larger than a goose's egg, was felt in the left inguinal region, extending some way into the scrotum. It appeared very elastic, and coughing gave a dubious impulse. When manipulated, the tumour gave him pain, and as the integuments were already much reddened, no real attempt was made to reduce it. The abdomen was somewhat distended, but not tender. There was no anxious expression, no vomiting, no great spontaneous pain, and the pulse was good. The patient was put to bed and a large enema given, of which only part could be retained. It brought away a small quantity of fæces. At 2 P.M. Dr. Roberts Law saw him, and ordered an injection of morphia over the tumour. At 4 P.M., as no alteration was observable in the tumour, the patient was taken into the operating-room and put under ether. After a very short preliminary attempt at taxis, an incision about two inches and a half long was made over the centre of the tumour, and the layers divided down to the sac. On passing the finger towards the abdomen to find the stricture, a small sharp-pointed body was felt protruding through the sac wall outside the external ring. This was seized by the forceps, withdrawn, and proved (microscopically) to be the end of a thin slip of bone, two inches long, by three-sixteenths of an inch broad at its widest part; to the other end of this was attached a fibrous shred, with the colour and odour of fæces. A director having been introduced into the opening in the sac, the sac wall was carefully opened on it; this was found very thick and friable; its internal surface was dark-red. The cavity was filled by a portion of intestine, attached to which were large masses of fat. In this intestine was found a corresponding hole to that in the sac wall, through which the bone was withdrawn. The edges of these holes were of a greyish colour and sloughy appearance. On passing a director through the hole in the upper surface of the gut, the point reappeared at the opposite surface under the fat, where a second opening was found, presenting the same characteristics; thus the bone evidently transfixed the intestine and skewered it in the sac. No obstruction was made out, but one band tighter than the rest was notched, and the finger was passed freely into the abdomen, but the intestine was found adhering to the sac. The contents of the sac were left in position, a drainage-tube was put into the lower angle of the wound, and the upper part was closed by sutures. The operation was performed antiseptically. After the operation the patient was allowed iced milk-and-water, and one grain of opium was given every six hours.

He passed a quiet night, and was not sick. No flatus passed by bowel. Next morning the pulse was 120, full; temperature 100·4°. The wound was dressed; the deep parts were healed; the drainage-tube was taken out. In the afternoon he vomited twice, and once in the evening, the vomit being curdled milk in thin colourless fluid. No flatus passed by bowel. On the 17th the stitches were taken out of wound, which was nearly healed. The parts around looked brawny and dark. During the 17th retching became more frequent, not much was brought up; the vomit was once only a little greenish. Eructations of wind very troublesome. No flatus passed per anum. The tongue remained moist. The patient took beef-tea, milk, and champagne freely. In the evening the pulse became weaker, and the abdomen slightly more distended. He passed a very restless night, dozing at intervals. In the morning the condition was much worse, the abdomen much more distended. Tongue still moist. Temperature 99·4°; pulse 124, much weaker. Urine, which had been drawn off by a catheter since operation, was now dark-brown, slightly albuminous, and contained altered blood-corpuscles. Nothing had passed by bowel. The finger was forced into the wound some distance, but let out no pus. The integuments round the wound were darker and more swollen. Ordered four ounces of brandy, and turpentine stupes to be applied to the abdomen. In the afternoon the pulse failed, and the limbs grew cold. Vomiting ceased almost entirely, the breathing became laboured, and death occurred at 11.45 P.M. on the 18th, seventy-nine hours after operation.

The necropsy (sixteen hours after death) was performed by the house-surgeon. On opening up the wound about a drachm of brownish stinking pus escaped from the sac. The interior of the sac was very dirty-looking. The piece of fat in the sac had become adherent to the walls. There was no constriction in the neck, the finger could be passed into the abdomen. On opening the abdomen the intestines were found much distended. They presented points of injection all over, and had become greasy, having lost their polish. There was no fluid in the abdomen. On turning up the coils from the inner opening of inguinal canal, the colon close to the sigmoid flexure was seen passing over the aperture, and on pulling it it was found to be partially engaged in it. When the neck of the sac was slit up, it was observed that part only of the circumference of the colon was drawn into the neck, and attached to it was the piece of fatty tissue in the sac. By the fact of one side of the bowel being implicated in the neck, the calibre of the gut was greatly diminished at that point; below this the intestine was flaccid and empty. On cutting out the piece of gut and opening it longitudinally, an appearance exactly like a diverticulum was presented, which, turned inside out, showed the entrance and exit holes of the bone. The mucous membrane round the one in the upper wall was livid, in the other one the edge was thin in consequence of the perforation in the mucous membrane being smaller than that in the outer coats. There was no mark of constriction, and, except just in the neighbourhood of the holes, the mucous membrane appeared healthy. The kidneys when opened showed somewhat diminished thickness of cortex, which was tougher than natural. The capsule stripped off readily enough, but left a slightly granular surface.

Remarks.—One may observe that in this case the usual symptoms of tight strangulation of the gut were absent, but, taking into consideration the advanced age of the patient, it was thought best to operate without unnecessary delay. The operation proved satisfactorily the impossibility of reduction.

The non-passage of flatus or other contents of the intestine after the operation may have been caused by the non-return of that portion included in the sac, but the lowered vitality incident to the patient's time of life more probably prevented the intestine resuming its normal functions.

The question arises, Would the formation of an artificial anus have by any possibility influenced the ultimate result?

BIRKENHEAD BOROUGH HOSPITAL.

POISONING WITH PHOSPHORUS.

(Under the care of Dr. STEVENSON.)

FOR the following notes we are indebted to Mr. F. Grenfell Baker, M.R.C.S., senior house-surgeon:—

B. W——, a young woman, aged twenty-two, was carried to the hospital at 6.45 P.M. on Nov. 27th, by a police constable who had found her about three-quarters of an hour previously running about the streets, with, as he said, "flames coming from her mouth and hands."

The patient was a robust, well-made, young woman, and when admitted was in a very excited state, and talking incoherently. Thick luminous fumes were issuing from the mouth with her breath, and on her hands were patches of a greenish blue-looking substance, which was also luminous in the dark. The woman refused to answer any questions relative to her condition, and did not complain of any pain. A powerful odour of phosphorus was apparent around her. A strong emetic of sulphate of zinc was at once administered in water, and emesis immediately afterwards occurred. The vomited matters consisted of large lumps of undigested meat and potatoes, which when placed in a dark room were luminous, and smelt strongly of phosphorus. In a few minutes a second emetic similar to the first was given, together with a large quantity of water, which was swallowed without difficulty, and in about three minutes returned, but without any phosphorescent odour or appearance. After this the patient expressed herself as being "all right," and, refusing to remain in hospital, was conveyed to the police court, where she was charged with attempting to commit suicide. She had not long been in the Bridewell, however, when her condition became so alarming that the authorities sent her back to the hospital, where she was admitted at nine o'clock the same night.

On admission she was perfectly conscious, though some-

Digitized by Google

what collapsed and very pale, and was constantly retching and bringing up small quantities of yellow mucus. She was immediately put to bed, with hot bottles to her feet. She complained of great thirst, with pain in the mouth and throat, but she would only occasionally speak, and then in a scarcely audible tone. The pupils were normal, pulse full and regular, and the breathing hurried and shallow. She was very drowsy, but was kept constantly awake. Small quantities of fluid, containing equal parts of milk and lime-water, were given at frequent intervals. The patient was getting very cold, and sweating profusely. There was no swelling or tenderness of the abdomen. At 12.30 A.M. no change had occurred. While the patient was being put to bed a half ounce pot, almost empty, of phosphorous paste for killing rats was found concealed about her dress. At 2 A.M. she was breathing freely, respiration thirty in the minute; temperature 100°, pulse 90, full and regular. Great pain in throat and mouth was complained of, and patient appeared to be in a stupid, half-conscious condition. The eyes were closed, and on being told to open them only twitching movements of the lids occurred. The pupils were normally dilated and responsive to light. Nothing could be got from the patient as to what she had taken, and the few words she uttered were too feebly spoken to be understood. The abdomen was very tense and tympanitic, but did not appear to be painful. An enema of castor oil with tincture of opium was given, which shortly afterwards brought away some normally-looking fæces; at the same time the urine was voided, but could not be examined on account of its being mixed with the enema. No phosphorous odour was observed about the evacuation. At this time the breath was still strongly of phosphorus, and the patient restless and sleepy. Milk at frequent intervals was given, together with a solution of morphia every four hours, and a large hot poultice to the abdomen.

Next morning at ten o'clock no change had occurred in her general condition. There seemed to be great tenderness over the throat and epigastrium. The patient appeared to be quite unable either to open her eyes or mouth, or in any way to move, as if from extreme weakness of the necessary muscles; temperature 101°; pulse 104, and irregular; respiration 26, and irregular. The pupils were normal, but there existed intense photophobia of both eyes. There was profuse perspiration. On examining the chest all the signs of commencing acute inflammation of the larger bronchi and the trachea were evident, and there was great difficulty in swallowing. Milk, together with the whites of eggs, were ordered to be given during the day, and ice to suck. Fifteen drops of tincture of opium in cinnamon water were given three times a day. At 11 A.M., temperature 101°; pulse 106; respiration 34. At 2 P.M., temperature 99°; pulse 96; respiration 30. At 4 P.M., temperature 98·6; pulse 68; respiration 24. At 6 P.M., temperature 97·4°; pulse 70, irregular and scarcely perceptible; respiration 24.

At 10 P.M., the nurse in charge sent to say the woman had died suddenly, and on seeing the body a few minutes later the house-surgeon found it lying on its back quite motionless, with no perceptible pulse, respiration, or heart's beat. The body was quite cold, temperature in the vagina 97°, eyes fixed, and she appeared in all respects to have expired. Artificial respiration was immediately resorted to, and in a few minutes the woman began to breathe very faintly, and at the end of half an hour's continuous efforts the pulse and heart's beat could just be detected, and respiration fairly carried on, though were irregular. The patient appeared to be quite unconscious. Several relapses occurred at frequent intervals, and artificial respiration had to be kept up till 1 A.M., when the breathing and pulse had much improved, though the temperature only stood at 97·4. The patient was coughing a good deal at this time, and loud râles could be heard all over the chest. No phosphorous odour was noticed in the breath.

Nov. 29th.—The patient had passed a very restless night, coughing continuously, but without any expectoration. She appeared very weak, and the mental condition was unchanged. The abdomen was distended and tympanitic, and the throat and the epigastrium were very sore. There was great photophobia. Temperature 98·8°; pulse 100, small and irregular; respiration 24, shallow and irregular. Moist râles were audible over the chest; heart's beat could not be felt, and on the slightest movement the patient appeared to be on the verge of suffocation. She coughed a good deal, but without any expectoration. At midday temperature 98·4; pulse 100; respiration 24. At 4 P.M., temperature 98·2°; pulse 80; respiration 35. At 6 P.M., temperature 96·8°; pulse 80; respiration 30. At 8 P.M., temperature 98·2°; pulse 78; respiration 30. No urine or fæces had been passed during the day, and in the evening the water was drawn off and found to be normal, without any phosphorescent appearance. The woman had taken iced milk and eggs at frequent intervals, and although there was constant retching, no vomiting occurred. The medicine was repeated during the day.

She passed a quiet night, and on the following morning answered questions put to her in a rational manner, but still in a very low, feeble tone. She complained of pain in the throat and slight epigastric tenderness. The tongue was clean, and the throat did not appear inflamed. She passed two pints of urine during the morning, which was quite normal. Milk was taken freely, and apparently without pain. She was still unable to fully open her eyes, or protrude the tongue. At 11 A.M., temperature 97°; pulse 100, irregular and very small; respiration 30. At 3 P.M., temperature 98°; pulse 100; respiration 24. At 7 P.M., temperature 98·4°; pulse 128; respiration 34. At 10 P.M., temperature 101°; pulse 90; respiration 32. At 12 temperature 98·4°; pulse 80; respiration 30. The same treatment was adopted as before.

On Dec. 1st the patient appeared to be altogether in a totally different condition. She spoke intelligently, and said she did not remember anything that had occurred during her illness, but admitted she took the poison. There was no abnominal pain or tenderness, though the abdomen was still somewhat distended and tympanitic. There was very little tenderness about the throat, and slight difficulty in swallowing. The medicine was discontinued, and the patient still kept on a diet of milk and egg, with some bread and butter. The urine and fæces were voided during the day, and appeared perfectly normal. Temperature 99°; pulse 100; respiration 25, at 10 A.M. At 10 P.M. the temperature was 98·8°; pulse 90; respiration 25. The eyes were fully opened, and tongue protruded at will.

Next day, but for general weakness, the patient appeared to have fully recovered—no pain or tenderness was anywhere experienced, and the abdomen was of the natural size. The temperature, pulse, and respiration were normal, and no sickness was complained of. The police authorities removed the patient to the Bridewell, from whence she was taken to the workhouse, where she remained for ten days, and was then allowed to return to her friends, being perfectly well.

During the whole time the woman was under observation no signs of jaundice were perceived.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Parasites in Muscle in Typhoid Fever.—Spontaneous Disappearance of Morphœa.—Lichen Ruber.—Cyst in Brain.—Aneurism by Anastomosis.—Suppuration in Larynx.—Mitral, Tricuspid, and Aortic Stenosis.—Tumour of Spermatic Cord.—Congenital Malformation of Rectum.

THE ordinary meeting of the Pathological Society was held on Tuesday, the 20th inst., J. Hutchinson, Esq., President, in the chair. An interesting communication from Mr. W. H. Power of the Local Government Board on the discovery of nematoid worms in the voluntary muscles in typhoid fever was read by Dr. G. Buchanan. Mr. Eve introduced the subject of laryngeal abscess in typhoid fever, and, on the request of the President, Drs. Greenfield and Taylor promised to bring other specimens illustrating it, and raise the discussion again.

Dr. G. BUCHANAN read a paper on Some Appearances, probably of Parasites, in the Voluntary Muscles of Enteric Fever. The observations which it described were made by his colleague, Mr. W. H. Power, who was led to investigate the subject by finding that an epidemic on board the training-ship *Cornwall*, supposed to be typhoid fever, was really trichinosis. He thereupon commenced the examination of the voluntary muscles in typhoid fever. The first

Digitized by Google

case examined was a young man in St. Thomas's Hospital, who died from peritonitis set up by perforation of a characteristic enteric ulcer. In the pectoral muscle were found what were taken to be parasitic worms, one or more of which were seen in each specimen, and, apparently from their movements, they were still alive. Their dimensions were wholly different from those of trichina spiralis, being about a quarter of it in length and breadth. They were thickest in the middle, with one end larger than the other. They resembled nematoid worms both in the proportion of their breadth and length, and in the presence of an interior canal, apparently interrupted by some intervening organ or tissue. Another case of undoubted typhoid dying in the Seamen's Hospital, under the care of Dr. Curnow, was also examined, and in it too the same bodies were found, but in neither case were they so plentiful as was at first supposed. They were not found in all muscles equally; none have been found in the diaphragm, nor are they uniformly disseminated through a given muscle. Many slides may be examined without meeting with one. Certain much smaller bodies, having a possible relation to the larger parasites, were also found more abundantly; they are with difficulty distinguished from the muscle, and any slight interference with the slide often results in their being lost sight of altogether. With advancing decomposition the parasites, but not the smaller bodies, were found to be more numerous.

The PRESIDENT referred to a living specimen shown at a former meeting. It was a young woman, aged twenty, under the care of Dr. Porter, who a year ago was brought to him suffering with well-marked patches of morphœa, or Addison's keloid. These patches were placed irregularly, but corresponded with definite areas of nerve distribution; there was a patch close in front of each ear, and several on one arm. At the time he took accurate notes of the case. Now, only twelve months after, they have all completely disappeared, the skin merely showing a little staining and thickening. The fact of the complete disappearance of patches of morphœa is well known, but he brought forward this case, as it was one of the best proofs of it that he had ever met with, and also showed how rapid this disappearance might be. He thought Dr. H. Fagge was one of the first to draw attention to it.—Mr. MORRANT BAKER referred to a man who was under Mr. Willett's care some months ago with large patches of morphœa on the thighs; he was lost sight of for a time, but came to the hospital recently, and the patches had almost entirely disappeared, and, according to the patient's account, this improvement occurred shortly after hæmorrhage from the bowels.

Mr. MORRANT BAKER described a case of Lichen Ruber, which he had shown as a living specimen at a recent meeting. The woman, fifty-three years of age, had been under his care at St. Bartholomew's Hospital for some months. The disease began two and a half years ago, more especially on the extensor aspect of the arms and legs, where it presented large rough, almost warty patches, with slight desquamation, deeply pigmented, not weeping, but with intense itching. Some of the tops of the papules were scratched off, and this gave in places an aspect of prurigo. On the elbows there were one or two patches which were not raised, and which were much more like lichen ruber. Great difference of opinion had been expressed by those who had seen this case, some calling it an eczema, others prurigo, or psoriasis or lichen; for his own part he should prefer to call it lichen; perhaps it was the form of disease called lichen psoriasis by the President.—The PRESIDENT had used the term lichen psoriasis mainly in order to teach that the two diseases are but one and the same; he considered that psoriasis admitted of polymorphism, and that so-called lichen ruber or planus was one of its polymorphic varieties. It was certainly cured by the same remedies as psoriasis; he supposed Mr. Baker was treating his case by arsenic and tar ointment.—Dr. PYE-SMITH should have called the case psoriasis, but as Mr. Baker had seen it in its earlier stages he was best able to make a diagnosis; he could not consider this distinction of great importance, as the two diseases were so closely allied. On the other hand, the distinctions between prurigo, eczema, and psoriasis or lichen were very marked and definite.—Mr. BAKER stated that one dermatologist had called it an eczema; another thought it was an example of an undescribed disease, and should have a name to itself.

Dr. EWART showed a ramifying Cyst in the Brain. A man, aged thirty-one, was admitted under Dr. Whipham's care into St. George's Hospital in 1878. He had been attacked eighteen months previously with severe headache and vomiting. He improved, but relapsed six months later, and again in January, 1878. Soon after this attack he showed signs of mental derangement. On admission into the hospital he was found to have, in addition to the headache and vomiting, numbness in both hands. The mind gave way, he became very violent, and death took place from coma. At the autopsy the right hemisphere of the brain was found to contain a cyst. The membranes over the interpeduncular space and on the under surface of each frontal lobe were found to be thickened, the thickening consisting of a thin membrane packed closely in a depression on the brain, and sending tubular sac-like prolongations into the brain. The cyst was contained in a distinct cavity with a very smooth surface, very irregular in shape from projecting bands and columns, apparently produced by the branches of the Sylvian artery; the lining membrane looked like that of the ventricles, from which, however, it was quite distinct; it was cellular in structure. The cyst was formed of a very delicate membrane, so folded on itself that there was no appreciable quantity of fluid in it. On microscopical examination the inner surface was seen to be mammillated; under the projections was a clear space with a double row of cells, and beneath that numerous capillaries ramified. The cerebral arteries were also peculiar. The anterior cerebrals arose more deeply than usual, being covered over by the thickened membranes, and were connected by two branches close together instead of by one only. Just beyond the second of these communicating arteries the left anterior cerebral appeared to end in a misshapen knob, from which many branches arose, and particularly two which continued on over the corpus callosum in the usual position of the anterior cerebrals. The right middle cerebral artery was larger than normal, with an unusual number of branches arranged irregularly, many of which were almost occluded by hypertrophy of the intima. He thought the cyst was dependent in some way upon the irregularity of the vessels. It was remarkable to find such a lesion borne so long without symptoms. The symptoms experienced at last were probably the result of the increased growth of the cyst, or of some inflammation set up by it.

Mr. EVE exhibited specimens and drawings of Aneurism by Anastomosis of the External Ear. A woman, twenty-one years of age, was in St. Bartholomew's Hospital, under Mr. T. Smith. She stated that at birth there was a small lump at the upper part of the pinna, which pulsated; it gradually increased, and when she was six years old it was removed by ligature; two years later another portion of the growth at the back of the ear was unsuccessfully treated by pins. The whole of the pinna behind the external auditory meatus was involved, enlarged, of a dull-red colour, soft, pulsating, with a humming murmur. The temporal and posterior auricular arteries were enlarged; on pressing the carotid artery on that side the tumour became flaccid. She suffered from hæmorrhage from time to time, which gradually became more frequent and abundant. Mr. Smith removed the whole pinna, with some surrounding skin, very little blood being lost. The growth consisted of a number of anastomosing capillaries, many of them embryonic in structure. The Malpighian layer of the cuticle was greatly hypertrophied, extending down in processes, some of which were branched; the sebaceous glands were also enlarged. He thought this, which was the result of increased blood-supply, was of great interest, in its bearing upon the similar changes seen around epitheliomata. He considered the growth to have sprung from a congenital nævoid tumour.—Mr. EVE also showed three specimens of Perichondritis of the Larynx. The first was removed from the body of a man who was attacked with dyspnœa while convalescing from variola. Tracheotomy was performed, but death occurred. There was œdema of the epiglottis and ary-epiglottidean folds. Two oval ulcers were observed beneath the posterior attachments of the true vocal cords, leading into cavities containing pus, in which lay the necrosed arytenoid cartilages; the upper and back part of the cricoid cartilage was also necrosed. The other two specimens were met with in patients who had died from typhoid fever, one of whom suffered from frequent intestinal hæmorrhage, the other had very high temperature; the condition of larynx was like that in the first case, except that the cricoid cartilage was not affected. Many authorities consider this state as brought about by extension of the typhoid or variolous ulceration down to the cartilages. Liebermeister regards it as the result of a diphtheritic inflammation, but Sestier holds that the abscesses are caused by the general tendency to

Digitized by Google

suppuration, gangrene, and necrosis met with in convalescents from typhoid fever; and in this opinion Mr. Eve concurred. In both cases of typhoid fever there had been special causes of debility—in neither of them were there other ulcers of the larynx; and the fact that the same condition is met with after variola, shows that it is not a specific effect of typhoid. Typhoid ulcers, however, may penetrate deeply.—Dr. GREENFIELD had met with these abscesses in a number of cases, he thought them quite common, and due to formation of pus either in connexion with the perichondrium or more externally. He believed it to occur during the period of acute illness, and that it often subsided. In many of his cases there had been no symptoms during life. The position of the abscess was very characteristic. He had never seen it in uncomplicated typhoid fever.—Dr. GOODHART suggested that these cases occurred in epidemics; for years he had not met with a case, and then in two years had seen four cases. He thought they sometimes started quite outside the cartilages.—Dr. DOUGLAS POWELL asked if there were any other abscesses, pyæmic or otherwise, in these cases. He thought Mr. Eve's first case might have been due to a variolous ulcer, as it occurred early.—Dr. GREENFIELD had no notes of his cases at hand, but there was no evidence of any other pyæmic or bone lesion in the last case he had seen; as a rule, he had found the abscesses in patients dying during the acute period from intense fever and deep ulceration.—Dr. TAYLOR had seen one case last year in a patient who had high fever for six weeks, and then had perforation and peritonitis; there was a large abscess. An American physician had noticed stenosis of the larynx as following typhoid fever.—The PRESIDENT asked Drs. Greenfield and Taylor to bring forward their cases and specimens at a subsequent meeting of the Society, so that they might appear in the Transactions of the Society.—Mr. EVE stated that in his first case death took place on the thirtieth day. In neither of them was there any other abscess or sign of pyæmia.

Dr. PEARSON IRVINE showed a Heart with Stenosis of Mitral, Aortic, and Tricuspid Valves. A woman, aged thirty-seven, had been sickly from birth, never able to run about like other children; seven years ago she had an attack of acute rheumatism. Death occurred from dyspnœa and exhaustion. In addition to the stenosis of the three orifices there was found a large clot in the left auricle which filled the cavity, except a passage for the blood from the pulmonary veins. Dr. Moxon showed a similar case to the Society about two years ago. An interesting question was whether the disease was congenital or acquired, or both; there was no pericarditis.—Dr. EWART had shown to the Society a case of mitral and tricuspid stenosis about two years ago, and in that also the left auricle was completely filled by a clot which was channeled out for the blood.—Dr. TAYLOR asked if there was a tricuspid presystolic murmur.—Dr. IRVINE replied that the heart was acting very irregularly, with a double ventricular systole; there was a distinct diastolic murmur, heard loudest over the lower end of the sternum, which did not lead up to the systole.

Mr. WALSHAM exhibited a Tumour of the Spermatic Cord removed by his friend Dr. Marshall, from a boy, aged four. When two years old he was treated for a congenital hydrocele, but on account of the pain he was unable to wear a truss. A fluctuating globular tumour was now noticed just outside the external abdominal ring; this disappeared, and was followed by another close to the globus major, which increased in size, and was removed. On section the tumour looked like a coiled tube. It was seen to be composed of a number of tubular systems of cells; in the centre was a space, next came a zone of dense cells without blood-vessels; then a zone of cells more loosely packed, and with bloodvessels; and outside a zone of cells in a fine reticulate stroma. The cells consisted of round nuclei in a small amount of protoplasm. In many points it was like a gumma, but there was no history of syphilis. He considered it to have developed from the remains of the Wolffian body, from its structure, its position, and from the fact that fœtal remains are oftentimes the source of morbid growths.—Dr. GOODHART stated that this tumour closely resembled one he and Mr. Butlin had examined for the Morbid Growths Committee, exhibited by Dr. Gairdner, and called a lymphoma. Several of the tumours had disappeared spontaneously, and the peculiar tubular structure appeared to offer the explanation of this fact, the cells being discharged into the spaces. In Mr. Walsham's case, too, one tumour had spontaneously disappeared.

The following card specimen was exhibited:—Persistent communication between Rectum and Genito-Urinary Tract in a new-born male child; by Mr. Shallock.

Dr. Heneage Gibbes demonstrated the stereoscopic effect with a high power of the microscope at the close of the meeting.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Debate on the Lunacy Laws.

AT a meeting of this Society held on the 12th inst., Mr. F. J. Gant, President, in the chair,

Dr. CLEMENT GODSON exhibited a specimen of Placenta Succenturia which he had removed from a patient three hours after delivery. Severe secondary hæmorrhage occurred, which almost proved fatal. He believed this variety of placenta was not uncommon, and urged the necessity of thorough examination in each case.

Dr. HARRINGTON TUKE read an address on the Lunacy Laws. He said that the question of the alteration of the Lunacy Law, and the abolition or purchase by the State of private asylums, had become recently of much public interest. The intimation of possible future legislation in the speech from the Throne, the report of the Select Committee of the House of Commons, some recent lunacy trials, and the Bill introduced by the member for Swansea, had contributed to render this one of the questions of the day. Mr. Dillwyn's Bill proposed the transference of the jurisdiction exercised by the Commissioners in Lunacy over the Metropolitan Asylums from them (the Commissioners) to the justices of the peace. He pointed out the folly of thus ignoring and wasting the patient labour of thirty-five years, during which the Commissioners in Lunacy, under their distinguished chairman, Lord Shaftesbury, had secured the reputation of being amongst the most useful and indispensable of public officials. He referred to an editorial article in a medical journal, which advocated the sweeping away of private asylums from the face of the earth, and thought this expression was ill-judged. The series of remarkable articles, avowedly written by Dr. Bucknill, were generalisations upon too few facts which were not fully substantiated; and while he (Dr. Tuke) fully recognised Dr. Bucknill as the first physician and the foremost writer and thinker in his branch of the profession, he felt obliged to almost entirely dissent from his views. Dr. Bucknill had shown much power and ability in his ideas for the destruction of existing institutions, but had no suggestions for their improvement; and, admitting that some private asylums were good, it would seem more reasonable to raise the standard of the inferior ones than to abolish them. He took objection to the assertion that "this question did not interest the medical profession generally." It was not alone the fifty medical proprietors of asylums who were thus attacked; but as there were 185,000 persons certified as insane during the last twenty years, and in each case one or more certificates of registered practitioners were required, the question of improper committal to asylums became one of general medical interest; and, again, as there were few families who, with or without asking for these certificates, would consign those nearest and dearest to them to asylums without previous consultation with their ordinary medical adviser, Dr. Tuke pointed out the importance of an accurate definition of the private asylums for the higher classes, as distinguished from those receiving paupers, whether from the large State asylums or from the various institutions conducted by ladies and others in which the insane were received. The objection against private asylums that most deeply affected the public mind was "that patients were kept in asylums for profit." Now, while it is the human lot to labour, profit must be one of its incentives, and it is for the opponents of private asylums to show that such incentive has ever led medical proprietors of private asylums to wrong-doing, to base and sordid economies, or to illegal admission or detention of their patients. As to illegal admission of patients, he asserted that there were the most careful precautions taken (which he described

Digitized by Google

in detail) to prevent such an occurrence, under the present lunacy law, and these had been so far successful. In a properly-conducted asylum illegal detention or admission would require the organisation of a vast and almost impossible conspiracy. The medical proprietor, his wife and family, the friends of the patient, "the signer of the order for confinement," the two certifying medical men, and the chaplain attending the asylum, must all join in one vast scheme of base and cruel wrong, and a case of such wrong-doing has never been adduced. Under any possible human code mistakes may occur, and we can only adopt the best means in our power to prevent them. As to the prolonged detention of patients after cure, it may fairly be demanded that such cases should be produced or some proof be given of their existence. In Dr. Tuke's experience his recovered patients had ever become his warm friends, and sometimes his frequent visitors; and this, he ventured to say, was the experience of all our psychological physicians. Regarding insanity essentially as a disease, the author was of opinion that patients might often with great advantage be placed under private medical care, but this was contrary to the opinion given by some of the opponents of private asylums, who appeared before the Committee of the House. One of the committee objected to "needy doctors," and said that patients were better in the hands of widows, clergymen, and others. Dr. Tuke thought it was well to consider what was to follow the abolition of private asylums. The patients might go to private care, as many do now; but, surely, this would rather strengthen than eliminate the so-called vicious principle of profit or otherwise. All the insane must be placed in large public hospitals. There are at present sixteen of these institutions in existence; if more are required they will follow the natural law of demand and supply. In his opinion the nearer an asylum can be made to resemble the home that the patient has lost, the more likely it will be, under proper medical treatment, to become a place of cure. Dr. Tuke apologised for the length of his paper, and for the necessity of omitting many interesting questions, and ventured to suggest that the real improvement of the speciality of medical treatment for the insane was in the hands of the medical profession at large. The ordinary medical attendant of patients in the higher class of society should make himself intimately acquainted with the treatment pursued, and the general character of the asylum to which such patient has been sent. The many petty and the few grave charges made against private asylums would dissolve in the clear light of more extended medical supervision. The knowledge of insanity would become more general, and in many ways the public mind would be set at rest upon the question whether or not the best and most humane treatment was secured for the most helpless part of the community.—Dr. SUTHERLAND said it was almost impossible for cases to be illegally detained. That very day a patient recently admitted, a colonel in the Guards, had complained of his detention; but on being given materials to write to the Commissioners in Lunacy he was wholly unable to do so. A patient, who had suicidal melancholia, was taken from his asylum contrary to medical advice, and on the same evening cut his throat when dining with his family. Others felt the protection and comfort of an asylum. A lady, who had been insane on four previous confinements, of her own free will went with her husband to the Commissioners and obtained permission to enter his asylum as a boarder. Under proper treatment a fifth attack of puerperal insanity was averted. The statement that patients were detained after recovery was unfounded.—Dr. ROGERS said he knew but little of the causes which had led the Legislature to think of abrogating or setting aside private asylums kept by medical men, of some two or three of which he had a very favourable knowledge; and he asked the author whether any facts had been brought before the Parliamentary Commission on private lunatic asylums in support of the allegations made against them.—Dr. NEWINGTON said there were as many cases of alleged improper detention fought out at the Select Committee coming from public asylums as from private, showing that it was a question of detention in any asylum of either class. As regards many lawsuits having arisen being used as an argument showing there were grounds for the accusation, he might say that only one lawsuit had ever proved successful against a medical man. The proprietors laboured under great disadvantages in answering the attacks on them, for, while they were sufficiently numerous to allow of a hostile movement being directed generally against them, all reply must of necessity become personal. He was sure this consideration had prevented many of the older generation of private asylum proprietors from speaking, and when they were silent it was not for the younger to say much. There were some absurdities in the conduct of these attacks—e.g., THE LANCET had said in an article that there was a pressing peril due to the private asylum system, which peril was that patients were discharged too soon, so as to increase the registration for cures. A few weeks after, an article in the *British Medical Journal* stated that it was on the detention of patients after their recovery that private asylums throve. Where two presumably equal authorities were in direct conflict, it may be supposed that their effect was neutralised. The general feeling educed by the Select Committee was that private asylums were improving, which opinion Dr. Bucknill had endorsed; indeed he had said that it was the right policy to try to improve them; yet suddenly, in the face of this theory, the cry was changed to one of abolition. It had been said that the interest of private asylum proprietors was to detain their patients. That was far from the truth; for, as had been said to him by an eminent member of the profession, if the patients in a private asylum could be changed every three months the proprietors would soon make their fortunes.—Dr. BUCKNILL wished to say a word with regard to the statistics adduced to indicate the large proportion of recoveries in private asylums. Unconsidered statistics may be made to prove anything. In the evidence given by the late Dr. Alexander Sutherland before the Select Committee in 1860, it was stated that out of 185 insane persons treated by him as single patients in lodgings, he had cured 74 per cent. Surprised at this large success under what are thought to be unfavourable circumstances, Dr. Bucknill referred to the last Reports of the Commissioners, when he found that, out of 5965 patients under treatment in private asylums during 1878, only 558 were discharged recovered, or 9·39 per cent. He did not hesitate to avow himself the author of the articles on Lunacy Law Reform, which had been so much discussed. He had never attempted to keep it secret, and had long ago admitted it publicly. It was surprising that with this knowledge Dr. Tuke should have stated that the author of these articles had arrived at his opinions without any foundation of fact upon which to rest them. He had facts enough, accumulated during nearly forty years of asylum experience, if without breach of professional or official duty he could state them. One fact he could repeat, which he stated to the Select Committee, that among the Chancery lunatics he visited he met with five who had recovered, and whom he considered to have been improperly detained; and he could not say that in none of these cases was there, in his opinion, any *mala fides* in the detention. He had tried to discuss the question with all courtesy and kindness towards his professional brethren, but it is not mainly a medical question, and it is not fair to discuss it on the merits of Dr. Tuke's asylum, or of any other good asylum. In criticising any social or legal asylum we have a right to refer not even to its average, but to its worst results; and in examining the private asylum system he had a right to refer to the management of the inferior asylums. Take one thing, the system of commissions for sending patients to asylums, which the Legislature has tried to stop, but which is still rife, at least in regard to pauper patients sent to private asylums. Then it is said that no cases of ill-treatment were discovered by the Select Committee in 1877. They were not inquired for, although a very suggestive fact was broadly stated by Mr. Cave, the chairman—viz., that you hardly ever find an asylum patient who does not think he has suffered unjustly. Why this almost universal feeling of unjust treatment in asylums if the inmates are well treated? It is not so in the domestic treatment of the insane, and he could fully endorse the strongly expressed opinion of Dr. Lockhart Robertson, that it would have been impossible for him to believe the increased happiness of patients removed from asylums into domestic life unless he had frequently seen it. Dr. Bucknill concluded:—"I have this evening been accused of having changed my opinion as to the undesirability of entirely abolishing private asylums. Upon enlarged experience I should be justified in so doing, but as a matter of fact I am of the same opinion still. I would not attempt to abolish any good private asylum which was well managed as a real hospital for the treatment of mental disease, or as a voluntary retreat for the chronic insane; but whenever it was necessary to imprison any insane person for a lengthened period on account of his being dangerous, that duty of locking a man up,

Digitized by Google

except for brief exigencies, I would entrust to no private individual. Imprisonment under any form is a duty of the State, and ought only to be imposed by the authority and the officers of the State, and in places provided by the State."—Dr. HACK TUKE, after complimenting the author of the paper for the good temper he had shown in a matter affecting his personal interest, said he thought there was a fallacy in the argument that the temptation to obtain profit is not peculiar to the proprietors of private asylums; the real point is that this profit is obtained from those who are more or less helpless. Rightly or wrongly, it is this which underlies the public feeling about these institutions. Not on the ground of a sufficient amount of proved abuse would he contemplate their abolition, but on account of the feeling excited in the public mind by the false position in which the proprietors were placed. It must, however, be remembered that Dr. Bucknill had met with five cases of improper detention, and therefore it was not mere vulgar fanatical clamour that one had to consider. The proprietors deserve our gratitude, but in their own interests he thought they had better allow their houses to become State asylums, and receive due compensation, instead of being starved out by the establishment of public asylums. As regards the statistics brought forward, they certainly surprised him, because they showed that the good private asylums superintended by medical men only cured about 2 per cent. more than those carried on by lay persons. If really true, the marked distinction one was accustomed to make between the two classes of asylums would hardly be justified. The way in which the Lunacy Commissioners group the English asylums when presenting their respective percentages of cures (and which he had quoted in the *Journal of Mental Science*) appeared to Dr. Tuke to be one which may be fairly adopted when the treatment pursued in private asylums was in question. It is true that although called "private," some of them contain paupers, but when these institutions were being discussed *all* private asylums were included, whether they receive pauper lunatics or not; in fact, Dr. Bucknill had animadverted on the treatment of the latter in some of these houses. Profit was, of course, made out of the paupers as well as the rich. The cures in county asylums are, according to the statistics of the commissioners, greater than in the licensed houses, whether metropolitan or provincial. To explain this by pointing out that licensed houses receive some pauper lunatics does not obviously meet the case. It does not account for the fact that asylums receiving only paupers have more recoveries than those receiving both classes; other reasons must be sought for, and may, no doubt, exist without any blame attaching to the proprietors of private asylums themselves. Quite fair, however, as the grouping of the various asylums by the commissioners appeared to him to be, for the particular purpose in view, it would be misleading if employed to ascertain the relative amount of insanity among the rich and the poor.—Dr. L. S. FORBES WINSLOW said the question of an alteration in the Lunacy Laws and the abolition of private asylums was one which has frequently arisen. Every great lunacy case of late years has been made an excuse for attacking private asylums and their proprietors; but it is rather significant that all the allegations brought against these institutions have failed, and their proprietors in every case have come out triumphantly. Statistics in reference to a comparison between private asylums and public ones, as regards the percentage of cures, prove nothing. There were at present in his institution between fifty and sixty inmates, but very few curable cases, for the simple reason that all cases deemed curable are discharged as such before the end of the year, and only chronic cases as a rule remain. He considered the matter as one in which the honour of medical men had been unjustly attacked, and there is no reason to assume that medical proprietors of asylums would behave dishonourably more than other medical men. He could name some celebrated physicians who have been and are proprietors of these institutions. Lord Shaftesbury gave evidence in 1859 which was opposed to private institutions, but in 1878, when the last Lunacy Committee sat, he said, in reply to a question as to the present state of private asylums: "At present, from a variety of causes, the licensed houses are in a far better condition in every sense of the word; more is expended on them by the proprietors, and I must do them the justice to say that the change is very great, and, so far as the evidence I gave in 1859 is correct, I should not give it now." This is the publicly-expressed opinion of the greatest living authority on lunacy matters. Lunacy legislation is a most difficult subject, but any clause in a subsequent Act which would protect the proprietors from unjust insinuation would be hailed with acclamation by a large body of medical men, whose sole desire is the cure of their patients.—Dr. TUKE, in reply, said that it was a private Bill which he had brought before the Medical Society, and one not purporting to be founded in any way on the report of the Committee. He declined altogether to discuss Mr. C. Reade's clever but sensational novels. He thanked Dr. Newington for his remarks, and said that the case of Hall *v.* Semple would never have arisen had Mr. Hall been sent to the charge of a medical man. As to the statistics he had brought forward, the two tables followed close on each other, but were not connected. For the purpose of his argument, the first table sufficed, which showed private asylum statistics to be at least equal, if not superior, to public ones in the number of recoveries. Dr. Hack Tuke's objection to private asylums "that profit is gained from the helpless and demented, and is therefore unworthily gained," was illogical; for it was not possible to treat the helpless and demented except through their guardians under the supervision appointed by the State. In the same category as children at school, many of them were quite as able to look after their own interests as elder boys; but in any case State asylums would be liable to the same objection. Dr. Sutherland had defended his father's statistics, and had offered his case-books for inspection. This was not necessary, for the objection to his figures was manifestly absurd. The late Dr. Sutherland out of a large number of patients selected the most curable to place under care in cottages, and hence his large percentage of cures. It was difficult to follow Dr. Bucknill over the large number of topics he had entered on; but on the question of giving and taking commissions, he agreed with Dr. Sutherland in saying that he had no knowledge of such a proceeding. Dr. Tuke then thanked the President and Fellows for the kind and patient hearing they had given to his paper, and the meeting adjourned.

Anatomy for Artists. By JOHN MARSHALL, F.R.S., F.R.C.S., Professor of Anatomy, Royal Academy of Arts; Professor of Surgery in University College, London, &c. &c. London: Smith, Elder and Co.

A Rule of Proportion for the Human Figure. By JOHN MARSHALL, F.R.S., &c. &c. London: Smith, Elder, and Co.

PROFESSOR MARSHALL has lectured for so many years on artistic anatomy at the Royal Academy and at the School of Design at South Kensington, that any work relating to a subject so familiar to him in all its bearings and details will be welcomed both by anatomists and artists. Indeed, the number of works on this interesting branch of study is very limited, and those which are of any real value to the ordinary artistic student are almost inaccessible to him. In the "Anatomy for Artists," Professor Marshall has given an anatomical description of the bones, joints, and muscles with such thoroughness, and in so clear and lucid a style, that the artist who can obtain a skeleton for reference will be quickly able to understand the structure, form, and mechanism of the human body. The surface forms dependent on the peculiar curves, eminences, and depressions belonging to each bone are most carefully described, and the changes in surface appearance produced by the various muscular movements are most clearly pointed out, so that these constitute the specially characteristic and most valuable features of the work. It will thus become the text-book for every artist who wishes to thoroughly master the anatomy of the human form in relation to the outward surface, and give him the explanation of those peculiarities of the figure with which every true student must become acquainted in order both to satisfy his own curiosity and to prevent his falling into error if he would depart in ever so little from the mere copying of his model. As Professor Marshall truly says in his most

Digitized by Google

philosophic induction, "With the aid of anatomy alone can the artist safely advance from the individual to the ideal, and attain to special or general conceptions of form." Not only, however, is the "Anatomy for Artists" a safe guide in art-anatomy, but the anatomist himself will profit greatly by a careful study of Professor Marshall's anatomical descriptions; and the concise and accurate manner in which these are given lends an additional charm to the work. We must add that the two hundred original drawings by Mr. J. S. Cuthbert are not only artistic, as we might have expected, but are also most scrupulously correct, and reflect great credit on his skill and taste. The volume itself is most elegantly printed and bound, and the publishers may be congratulated for issuing a work on art-anatomy which in its very appearance is itself artistic.

In "A Rule of Proportion for the Human Figure" Professor Marshall has published six plates, giving the measurements of length, breadth, and depth of the different parts of the male and female figure, and from these he has deduced a rule of proportion which he conceives is more correct and more easily grasped and remembered than the older systems of proportion put forward by Dürer, Carus, Zeising, and others. Scientific accuracy is impossible in such a matter as this, but Professor Marshall's rule is, we think, more useful than the formula generally employed by art-students, and is certainly to be commended for its simplicity in comparison with some of the ingenious and elaborate systems which have been proffered for our guidance. In this rule the trunk is divided into four equal parts, corresponding with the length of the head, as measured from the vertex to below the chin, and each of these parts is subdivisible into nine smaller units. The upper and lower limbs and their various segments can also be readily expressed in *heads and units*, and the same applies to transverse and antero-posterior as well as to longitudinal measurements. It is certainly interesting to find that Professor Marshall expresses the standing height of his typical male figure in 67 units, whilst Dr. Beddoe gives 67·3 inches as the average stature of the male inhabitants of Great Britain, so that Professor Marshall's units may practically be taken as inches. The special value and necessity of being acquainted with the law of proportion must be self-evident to every artist who would wish to avoid errors which mar the best works of some of our greatest sculptors and painters. Individual examples deviate in nature from these proportions, and so the artist must diverge from them also, according to the special type or character he is desirous of portraying, but they will afford him a safe point of departure, and indicate the limits within which his creative powers must be restrained.

Traité Clinique et Pratique de la Phthisie Pulmonaire et des Maladies Tuberculeuses des divers Organes. Par Dr. H. LEBERT. Paris: Delahaye. 1879.

THERE is nothing, either on the title-page or in the text, to indicate that this is a posthumous work—the last literary effort of one of the most indefatigable observers of our day. The fresh vigour of the style, the manner in which—himself a pioneer in the path—the author has kept up with the advancing knowledge of our day, are somewhat surprising when we remember that he died a year before this book issued from the press. Not that he has embraced all the acquisitions to knowledge of tuberculosis, especially those of its minute pathology, for the book is mainly based upon personal observation; but here and there we come upon indications of his interest in and acquaintance with doctrines which have been quite recently promulgated. To take one example. In speaking of the pathology of phthisis, he alludes to the recent work of Charcot, which has gone so far to displace the doctrines of Virchow in a field of which Lebert himself was one of the earliest workers. A German, he passed much of his life in France, and in this particular branch of pathology he identified himself more or less with the French school. As an evidence of the versatility of his powers, we may mention that, besides his treatise on Pathological Anatomy and several volumes on diseases of the respiratory organs, he has published works on cholera, typhus fever, diseases of the stomach, congenital diseases of the heart, and urinary diseases, on most of which subjects he is a contributor to Ziemssen's Cyclopædia.

Lebert died in August, 1878, at the age of sixty-five, and his published works cover a period of forty years. Upon the subject of phthisis and tubercular diseases generally his name follows close upon that of Laennec and Louis, although it would be saying too much to rank him on a level with these masters. One of his earliest and best known pathological contributions was the endeavour to establish the specificity of tubercle from its microscopical characters, and although somewhat shaken in his belief by the works of Reinhardt and Virchow, he lived to see a reversion to the doctrine of unity of tubercular disease widely accepted.

The book before us deals with almost the whole range of tubercular affections, chiefly, however, with pulmonary phthisis. In one sense it is not likely to be widely read, for it is not perfect as a literary effort, nor useful for educational purposes. Had the author lived he might in many ways have rendered it more attractive as well as more profound. Its chief merit lies in the fact that it contains the sum and substance of his life's experience in these diseases. It does not offer much that is novel, or, indeed, suggestive, but it is a sound clinical and pathological record, and on every page bears the impress of careful personal observation. In this it differs from many writings upon this much-discussed subject, and compares favourably with them.

Necessarily such a work is liable to lead to rather undue self-assertion on the part of its author, and we cannot absolve Lebert from this fault. His introduction reviews his own labours in the natural history of pulmonary diseases, and he lays claim to priority in many observations, amongst which may be cited that of the inoculability of tubercle. The book is divided into five parts. The first deals with etiology and pathogeny, where he sums up against any doctrine of specificity (contrary to his earlier opinions), seeing only in tuberculosis the outcome of depraved nutrition. The second part treats of the symptoms of pulmonary phthisis, and, in turn, of lymphatic, uro-genital, cerebral and meningeal, and peritoneal tuberculosis. There is nothing which calls for special comment in this chapter, but exception may be taken to his description of the symptoms of bronchial adenopathy, for he gives only those of great enlargement, which are surely rare in primary tubercular disease. The third part deals with the pathological anatomy; and the fourth with the diagnosis and prognosis of each of the above affections. Lastly, a long section is devoted to treatment. It opens with an expression of satisfaction at the revival of therapeutics, and its new foundations upon physiological knowledge, and he happily contrasts the old empirical antiphlogistic treatment of phthisis with the modern and more rational aims at prophylaxis through climatic influences. Indeed, the chapters devoted to climatology are some of the best in the book, for they are evidently penned by one who knew personally the districts of which he writes.

HEALTH OF DUBLIN.—During the week ending the 3rd inst., the deaths registered exceeded the number of births by 31, representing an annual death-rate of 42·8 in every 1000 of the population. Zymotic diseases caused 65 deaths, 13 of which were due to whooping-cough, and 4 to small-pox. As regards the latter disease, 11 fresh cases were admitted during the week into the principal Dublin hospitals, and 8 were discharged, leaving 46 under treatment at the close of the week.

THE LANCET.

LONDON: SATURDAY, APRIL 24, 1880.

WHAT is a Workhouse Infirmary? We are not at the moment concerned with the legal definition, or classification under a particular Act of Parliament—for example, that by which the district sick asylums of the metropolis are constituted,—but with the broad and practical question: What is the purpose and scope of an infirmary attached to a Poor-law district, including the "sick-wards" comprised in a workhouse? Is this establishment, under whatever description it may fall, a pauper *hospital?* And if it is, what sick persons should be accommodated within its walls—paupers who are invalided, or sick persons who are pauperised by their sickness? There is an important economic distinction between the two classes of possible inmates specified. If the infirmaries, or wards for the sick, attached to workhouses are provided simply for the medical care of the paupers who may fall ill in the workhouses, that is one thing, and the efficiency of these departments must be tested solely with regard to the requirements of the houses to which they belong. If, on the other hand, the infirmaries of workhouses are to be viewed as hospitals for the districts with which they are connected, then it follows that the Poor-law system contemplates something more than the mere relief of sick paupers, and includes in its programme an attempt to cure the maladies which contribute to the increase of pauperism by disabling and throwing upon the rates the poor who fall sick, and not unfrequently their families also.

We are anxious to consider this question apart from the wider topic of public provision for the sick, because it is important to ascertain precisely what the State contemplates by the hospital work in which it is officially engaged. It would be easy to assume that the infirmaries and sick wards connected with workhouses in Poor-law districts were intended solely for the accommodation of sick persons who are already paupers, but that the recent policy of ordering the great majority of poor persons applying for public charity into the workhouses disposes of the hypothesis. If a sick man applies for relief, and is sent to the workhouse, he is practically sent to the workhouse infirmary, and in so far as his poverty may be the result of his illness, it is, or should, clearly, be, the purpose of the guardians to see that his cure is carried out with the greatest possible celerity, and that he has recovered at least so far as to remove any danger of a relapse before he resumes the struggle for self-support. Unless what the Poor-law authorities are doing is made plain, unless they themselves understand it as an economic proposition, nothing is more likely than that, by stinting the means of thorough and prompt treatment in the workhouse infirmaries, guardians of the poor—or, more correctly, guardians of the rates—may be augmenting the burden they aim to reduce. Obviously it cannot be a wise policy to hurry cases of acute disease—needing for its remedy active measures and more or less costly agents and appliances—into an institution constructed, furnished, and provided for the accommodation of chronic cases. This would be a facile mode of multiplying the already large number of "permanent sick" in every district, and could not for a moment be regarded as sound financial policy. An infirmary which may answer fairly well as a department for the sick inmates of a workhouse who are already pauperised, and whom it is not deemed worth while to *cure*, is not necessarily a suitable establishment to be employed as a Poor-law hospital. The consideration on which we are anxious to insist is that the workhouse infirmaries must be made efficient as hospitals for recent or acute cases, if what is called the "labour-test" system is to be carried to its legitimate lengths.

An endeavour has frequently been made in these columns to show how large a proportion of the poverty that calls for public relief is the direct effect of illness. This fact is so obvious that to ignore it must be to persist in disregarding one of the frequent and most constant factors of pauperism. It would be a sound commercial policy to minimise the cause of ceaseless demands on the purse of the ratepayer by improving the machinery for curing disease. It is not only necessary, but expedient, that the Poor-law system should include an organisation for "medical relief," and that the service for which this agency is created should extend beyond the mere casual care of sick paupers. If there were no special reasons to inquire whether the workhouse infirmaries are performing their functions adequately, it would be important to exercise a watchful care lest they failed to grapple successfully with the small percentage of acute cases occurring among the inmates of workhouses. It would be a calamity if those who are merely classed as "paupers" should be disabled from an effort to enter the ranks of the bread-winning population by the neglect of curable disease. How much more regrettable would it be to find that sick persons plunged in poverty by their maladies were not provided with the means of recovery, but, from false notions of economy, were permitted to drift into the condition of chronic invalids, permanently dependent on the public rates!

This is evidently a matter of high interest and pressing moment. We invite the co-operation of medical officers of workhouses in an attempt to ascertain how far the infirmaries and sick wards attached to these establishments are of a character, and so conducted, as to serve the purpose of Poor-law hospitals for the cure of recent disease. It is plain that they ought to be efficient in this particular. Our standpoint in dealing with this question will be essentially *medical*. The changed policy of Poor-law relief places the workhouse infirmaries on the footing of general hospitals, and, making the most modest requirements as to the level of their efficiency, it is a duty the profession owes the public to inquire whether these institutions throughout the country are adequate to the need that exists, and which they are required to satisfy. We do not apprehend any difficulty in carrying out an inquiry which is of the most vital interest to the ratepayers generally, and we look with every confidence to the aid of those of our brethren who are engaged in the treatment of the sick poor under the Poor-law system, both those who are responsible for the hospital work accomplished, and those who, being in medical charge of the districts from which the inmates of workhouse infirmaries are received, may be able to help us in arriving

Digitized by Google

at a just conclusion as to the number and character of the recent and acute cases so disposed. The amount of clinical material in these institutions must be very large. It is a pity, even on scientific grounds alone, that this should be sacrificed.

THE Report of the Medical Officer of the Local Government Board for the year 1878, delayed in appearance by the illness and death of Dr. SEATON, has at length been published. It has been prepared by Dr. BUCHANAN, the present medical officer of the Board, and notwithstanding that he signs himself in regard to this Report as assistant medical officer, it must be looked upon as the first annual report, as Medical Officer, from his pen. The contents of the Report are of unusual interest, if only for the reason that they in part refer to the year in which the question of so-called "animal vaccination" was forced so prominently and persistently upon professional and public attention, and they throw a fuller light than has yet been had upon the views of the Local Government Board and of its medical adviser on this important subject. They, moreover, deal with other matters of abiding and equally great interest in the sanitary administration of the kingdom.

Briefly noting the gratifying illustrations the Report affords of the steadily progressive improvement which is being gained by the present arrangements for public vaccination in the kingdom, not only in the *quantity* but more especially in the *quality* of the vaccination (and notably in the quantity and quality of the vaccination in the metropolis, the least satisfactorily vaccinated district in the kingdom), we pass on at once to offer some observations on the part of the Report relating to Animal Vaccination. This is touched upon both in its pathological and its administrative aspects. Taking the latter aspect first, it is to be observed that Dr. BUCHANAN adheres to the results of Dr. SEATON'S personal inquiry, made in 1878, into the use of vaccine lymph cultivated upon calves, and which had previously been made known by Dr. BALLARD during the progress of the Medical Conference on Animal Vaccination, held several months ago. Dr. SEATON appears to have been satisfied in the course of his investigation that while difficulties which had been encountered in the transmission from animal to animal of lymph derived in the first instance from a natural source of cow-pox had practically ceased, there still remained a marked difference in the degree of certainty with which a desired result in vaccination could be produced with fresh lymph taken direct from the calf, as compared with fresh lymph taken direct from a child. In the most experienced hands there was a proportion of failures in successfully vaccinating with fresh animal lymph, such as is not known by experienced vaccinators with humanised lymph in this country. "These failures to obtain complete results (with animal lymph) had in Berlin led to a large proportion of the children receiving an imperfect degree of protection against small-pox, and at Amsterdam and the Hague they led to the practice of making a much larger number of insertions than were regarded as necessary for protection against small-pox, merely because the operator expected that some of the insertions would fail." To introduce then vaccination with *animal* lymph, with our present knowledge of the practice, into the system of public vaccination in force in England, would be to introduce not merely a hitherto unknown degree of uncertainty into its results, but also, in consequence of this uncertainty, to further certain methods of operation which would not be likely to find favour here, and which would tend to discredit vaccination. It is improbable that English parents, who, as a rule, dislike even our regulation number of four or five insertions, and in private practice too frequently successfully contend with their medical attendant for two insertions only, would allow their children to be subjected to *ten* insertions, or permit a second vaccination to make good imperfections of the first at the end of the day week!

"The substitution of certainty for uncertainty of success in the performance of vaccination," writes Dr. SEATON in an uncompleted memoir on this subject quoted by Dr. BUCHANAN, "was the great purpose of the reorganisation of vaccination arrangements which took place in England, in consequence of the official inquiry in 1859-64 into the state of vaccination in this country—a reorganisation which had been and is working with the most satisfactory results. To admit into our system, and stamp with the sanction of Government as one of equal value, a plan to which the main objection is uncertainty, would seem to me to be an inconsistent and retrograde step." Moreover, Dr. SEATON indicates that there is no experience with animal vaccination under the circumstances of a system of vaccination such as exists here, and that it is an error to speak of vaccination from the calf to the arm in Belgium (whence our knowledge of animal vaccination has been chiefly derived) as a "National System." There, as in this country, the vaccination generally in use, both public and private, is with humanised lymph from arm to arm. Nevertheless, although the Local Government Board is responsibly concerned with the arrangements for public vaccination alone—with regard to which, according to its Medical Officer, no ground has yet been shown that would justify a fundamental change; but, on the contrary, the evidence in the possession of the Board tends strongly to confirm the soundness of those arrangements—further study is being made on the subject in its various aspects, and it is intimated that it may prove desirable to make special arrangements to this end.

With regard to the pathological aspects of the question, Dr. KLEIN, under the supervision of the Medical Officer, of Dr. BURDON-SANDERSON, and of Mr. CEELY of Aylesbury, is engaged, under instructions from the Local Government Board, in carrying out a series of researches intended to settle the disputed point whether vaccinia can be produced in bovine animals by inoculation with the lymph of human small-pox. At the end of 1878 Dr. KLEIN had not obtained any affirmative result, although his operations had extended to sixteen heifers and fifteen milch cows. It is intended, as opportunity serves, to prosecute the experiments further, and for the present the details of the observations are withheld.

One only of the reports of the local inquiries as to the prevalence of disease, directed to be made by the Local Government Board, is reproduced in the appendix of the Report—namely, Mr. W. H. POWER'S report on a strange and fatal skin disease among infants at Loughton, in Essex, that proved to be due to the presence of arsenic in "violet powder" used for nursery purposes—a report already familiar

Digitized by Google

to our readers. The mass of the Medical Officer's Report, and that which forms its chief feature, is constituted by the third and concluding portion of Dr. BALLARD'S report on Effluvium Nuisances. This portion of the report is occupied with the nuisances arising in connexion with branches of industry in which mineral substances are principally dealt with, and nuisances in connexion with branches of industry in which matters of mixed origin (animal, vegetable, and mineral) are dealt with. The Medical Officer takes occasion of the completion of Dr. BALLARD'S great inquiry, which was entered upon in 1875, to offer some general observations upon its scope and results. He shows that its objects were, first, to learn the extent to which the public health is injured by one or another offensive trade or trade process; and, secondly, to ascertain in what measure and under what circumstances nuisance and injury to health can be avoided. In both directions the inquiry has been prolific of substantial results. Although in the first direction Dr. BALLARD was unable, during the time at his disposal, "to apply," as Dr. BUCHANAN phrases it, "the numerical method to the differential investigation of sickness and mortality, as influenced by proximity to offensive trade," he has brought together a great quantity of information from his own observation and the observations of others, which proves the large, although indeterminate, part which effluvium nuisances play in causing one place to be less wholesome than another. In the second direction of inquiry the report leaves little or nothing to be desired. Dr. BALLARD makes it quite evident that "nearly all the businesses that are now in a serious degree offensive may be carried on either without offence or with such important reduction of offence as shall make it tolerable or even trivial." This is the fact that it is important the Legislature and sanitary authorities should clearly apprehend, and it is comparatively unimportant, except as indicative of the moral responsibility of manufacturers, that, as Dr. Ballard points out, it is as much to their interest (pecuniarily) as to the interest of the public that the emanations from offensive processes should be arrested. Let us hope that the new President of the Local Government Board (whoever he may be) will see and take action upon the results derived from Dr. BALLARD'S inquiry, and particularly that he will give attention to the necessity of putting a stop to that form of perpetuation of manufacturing nuisances which may be studied on the banks of the Thames below Blackwall on the one bank and Woolwich on the other. There may be seen established and establishing themselves the offensive trades thrust out of London, without any check upon their reckless repetition of offence in their new location, heedless of the populations growing up about them, and rejoicing in the acquisition of certain vested rights, as it were, of producing nuisance. And this scandalous phenomenon is not peculiar to the Thames.

Dr. BALLARD'S Report in a complete form ought to be issued as early as practicable by the Local Government Board.

WE commented a few weeks ago on a scheme for covering London with provident dispensaries, in organic relation with London hospitals, to be built by a joint-stock company. Charity, in the eleemosynary sense of the word, is to have no part in the scheme. The members are to have the choice of their own medical men, and in extreme cases to have a claim on hospitals for admission and on the members of staffs of hospitals for their advice in consultation. The scheme is large and bold. It is promoted by Mr. STANSFELD, Sir CHARLES TREVELYAN, Sir RUTHERFORD ALCOCK, Dr. ROGERS, Dr. FAIRLIE CLARKE, and others. Reliance for the carrying out of this scheme is placed not, as we have said, on the almsgiving public, but on men of business, who, it is believed, will advance capital in a joint-stock way to supply the necessary buildings, and on the members of the large friendly societies, whose organising and administrative faculty has already been tested in the creation of large funds for providing against days of sickness. One kind of such associations is especially praised by the promoters of the London scheme—viz., that to be seen in several provincial towns, such as Northampton, Derby, and Scarborough, where the Friendly Societies, distinct in other respects, have combined for medical purposes to form a Medical Association for attendance not only on their own members, but on all and sundry other persons, without inquiry as to means or circumstances, who chose to affiliate themselves with such an association. Finally, the promoters—perceiving, what is very obvious, that such a scheme will require large funds,—though declining alms from private persons, hope to make out a strong claim when the redivision of the City Charities takes place, which have recently been under investigation by a Roya Commission.

Such are the outlines of the scheme which was brought under our notice in March, and which on Saturday last was adopted unanimously by a gathering, said to be large and representative, at the Cannon-street Hotel. The press of London has pretty unanimously accorded its approval of the scheme. There can be but one opinion as to the desirableness of reducing the amount of gratuitous medical service, both in the interest of the little-rewarded medical man and of the industrial classes, who are fast learning the value of their own services. So far as this scheme is calculated to promote this end it has our hearty approval. It is certain that the medical profession has suffered deeply from being made so cheaply and lightly available by the public. So far has this gone that there is an impression abroad that a medical man is bound to obey anybody's call night or day. His leisure may be broken, his night's rest lost, his health compromised at anybody's pleasure, and any previous inquiry as to remuneration will be considered vulgar at least, and probably unwarrantable. Men do not so ill use those who give them bread, and even to the publican who serves them with so much questionable stuff they pay an amount of money that would amply reward a private practitioner. People who give sixpence a day all the year round for beer cannot find sixpence a week for medical purposes, and become semi-paupers if they catch a cold or graze a finger. This state of things is thoroughly unreasonable, and must end. It is so unjust and demoralising that medical men will not much longer be found willing to take so-called honorary offices where such work is expected of them. We can only be thankful, therefore, to public men who give very valuable time to the amelioration of such a state of matters. Not that we would be understood to en-

Digitized by Google

dense all the particulars of the actual scheme before us, or be thought to believe that such a meeting as that of Saturday is "large and representative" enough to carry it into execution. We do not see that the meeting of Saturday advanced the scheme at all. All the persons present have been of the same opinion any time the last ten years. The objections which we urged in March were unregarded, and must, therefore, be repeated. The medical profession was very inadequately represented, and the representatives of the existing medical charities were also conspicuous by their absence. It was represented that under this scheme members and their families would have the choice of a medical man, whereas the provincial schemes held up for imitation involve the dislocation of old medical relations and the substitution of a new and a very much underpaid medical attendant. The necessity for a joint-stock company seriously complicates the project. The proposal may have charms for men with commercial proclivities, but it does not seem likely to attract capital. Finally, we are disclaimed the idea of admitting all comers to the benefit of these institutions, as is done in the associations to be copied. Unless this is attended to the medical profession will be injured. With these serious qualifications we are glad to approve the movement in question.

A DEBATE on "bone-setting" is an unusual event in the annals of a learned Society; but there can be no question as to the utility of such a discussion as that which took place at the last meeting of the Clinical Society. Enough was said to show that it is time that attention was thoroughly directed to this subject; for more than one speaker avowed of his own knowledge that cases often fell into the hands of bone-setters after having passed from under the care of the legitimate practitioner. In one sense surgeons have to blame themselves for this, for failing to recognise the true nature of the case, they do not resort to measures which are taken by the bone-setters as a matter of routine, and not only without any basis of knowledge, but with a great parade of ignorance. No doubt the mischief that the members of the bone-setting fraternity do is very great; several instances, some with fatal results, were related the other evening; but often their rule-of-thumb practice and ignorant presumption succeed in restoring utility to a limb condemned to prolonged immobility by the surgeon, who disregarded the symptoms of the case. No doubt the "cases that bone-setters cure" are—as pointed out by Sir JAMES PAGET in his Clinical Lectures and Essays, the best guide extant on the subject—mainly those of adhesions within or (more often) *without* the joint, the result of some trifling injury or sprain; and in cases such as these the facility of reduction affords ground for the pretensions of the bone-setter.

But what shall we say of that other class of cases above alluded to, where people who follow these practices do irreparable mischief? It has been abundantly shown that many times an inflamed joint has been so damaged by manipulation as to call for its subsequent excision. In cases where absolute rest and rest alone is of avail in aiding recovery of function, to violently move the part is a serious malpraxis. It is important, then, that the example set by the bone-setters should not be followed, but the treatment of joint disease be carried out on thoroughly scientific grounds, founded, as all such treatment should be, upon sound pathological knowledge. In a recent review of the progress of surgery—published, rather curiously, in the leading daily journal—the writer fell into a grave error in making a general deduction that "a part of the body which has movement for its special function cannot be restored to integrity by the influence of rest." To be sure, he takes his examples only from injuries, but the statement is made so broadly as to lead the non-medical reader to conclude that, no matter what is the condition of a joint, movement and not rest will restore its integrity. The broad conclusion then is this: there are cases (mostly of sprains) which can be rapidly and readily cured by the manipulations which have been falsely called "bone-setting," and there are other cases (mostly of inflammatory disease) which are made infinitely worse by such measures, and which can only be rationally treated on a plan that forbids all movement whatever.

Annotations.

"Ne quid nimis."

RELIGIOUS TESTS AT KING'S COLLEGE.

IN another column we print a correspondence which speaks for itself, and the story it tells is certainly one strangely out of harmony with the spirit of the times. Of course, we can understand the position occupied by King's College as an endowed corporation, and to a certain extent sympathise with the struggle which the trustees under its Charter are engaged in to maintain at least the semblance of consistency; but the futility of their endeavours and the grotesque predicament in which the effort made places the College authorities are rendered singularly apparent by the letter of Mr. Cunningham, the secretary. Tests are, it seems, rigidly enforced "except in the case of teachers of foreign languages!" This is probably one of the funniest statements ever put on paper. Accepting King's College as the bulwark of Protestantism in London, whence, we may ask, do the champions of Church of Englandism expect to encounter the machinations of their traditional foes? If it be Popery against which they are to protect the youth of the metropolis, what rôle is the dreaded Jesuit so likely to assume as that of "teacher of foreign languages?" If the bugbear be Rationalism, Positivism or Nihilism, surely the "teacher of foreign languages" is the very man to be kept out. In short, the wolf, to whatever species he may belong, is far more likely to come disguised under the skin of a teacher of foreign languages than that of an ophthalmic surgeon. The authorities of King's College should look to this matter. Their views of duty as expounded by the secretary are as short-sighted as they are distorted. If King's College desires to retain the respect of sturdy Churchmen, the reconsideration of its policy must not be delayed. It is absurd to make a parade of keeping guard at some small wicket for the sake of a Charter when the front door is left open, and special facilities are offered for the ingress of the enemy in his most probable guise.

NURSING AT GUY'S.

THE President and Governors of Guy's Hospital have recently expressed an unequivocal opinion on Miss Lonsdale's notorious article in the *Nineteenth Century* on the Nursing at Guy's Hospital. It seems that about a fortnight ago Dr. Habershon, the senior physician, stated in a

Digitized by Google

letter to Miss Lonsdale that he thought her presence in the wards was not desirable, and that he hoped none of his colleagues would allow her to go round with him. This letter Miss Lonsdale at once submitted to the chivalrous treasurer, who thereupon wrote to Dr. Habershon, telling him that his letter to Miss Lonsdale, and all the circumstances connected with it, should be brought before the Court of Committees, and suggesting that some explanation would be expected from Dr. Habershon, for thus summarily treating "a lady in this hospital without any reference to me in the first instance as the chief executive authority." Dr. Habershon replied that he did not consider his refusal to allow Miss Lonsdale to accompany him round the wards an interference with the treasurer's authority, and that as his own moral and professional character, as well as that of his colleagues, had been assailed by this lady-pupil in the current number of the *Nineteenth Century*, he claimed the right to protect himself without reference to the treasurer "in the first instance as the chief executive authority." The terms of this letter were unanimously adopted by all Dr. Habershon's colleagues, who, in a letter addressed to the President and Governors, called attention to the charges brought by Miss Lonsdale against the honorary medical officers and students in the articles referred to.

At the Court of Committees, held on the 14th inst., after the reading of the correspondence between the Treasurer and Dr. Habershon and the letter addressed to the President and Governors by the medical staff, it was resolved that the Court of Committees disapproved of any publication relating to the management of the affairs of the hospital by any person attached to the hospital in any capacity. The Court, therefore, felt that, under the circumstances, Dr. Habershon was justified in declining to allow Miss Lonsdale to be present while he was visiting the patients in his wards. As Miss Lonsdale's engagement at the hospital was just on the eve of expiring, it was not thought necessary or desirable to proceed to the extremity of expelling her. The Guy's staff and students may now, however, congratulate themselves that they are at length rid of the author of the alleged "biographical romance," *Sister Dora*.

URBAN AND RURAL FATALITY OF DIPHTHERIA.

AT the last meeting of the Metropolitan Association of Medical Officers of Health on the 16th inst., two interesting papers were read dealing with the prevalence and fatality of diphtheria. Dr. Alfred Hill, medical officer of health for Birmingham, described in detail the fatal prevalence of diphtheria in that town during 1879; while Mr. A. Wynter Blyth's paper was entitled "Prevention and Propagation of Diphtheria," and was based upon the author's experience in a combined sanitary district in Devonshire, which is mainly rural in character. In one essential particular the authors of these two papers appear to have arrived at exactly opposite conclusions. Dr. Hill dwells upon the fact that, although diphtheria may be said to be endemic in Birmingham, it never appears to assume an epidemic form, and states that he was unable to trace any connexion between the fatal cases in 1879. Mr. Wynter Blyth, on the other hand, insists that the disease is intensely contagious. It is beyond all doubt that very many virulent outbreaks of diphtheria in recent years have occurred in rural villages, whereas the disease seldom assumes a similarly epidemic form in large towns. In the discussion which followed the reading of the two papers these facts were freely admitted, and the question was almost suggested, whether urban and rural diphtheria can be one and the same disease. Dr. Dudfield of Kensington expressed a doubt whether all the deaths referred to diphtheria in the metropolis were correctly diagnosed, and stated that during many years' experience in Kensington he had never known two cases occur in one house, even where isolation was an impossibility. Dr. Tripe of Hackney attributed the increased fatality of diphtheria in London to more general connexion with the main-drainage system of the metropolis. It is a fact that the fatality of diphtheria in London during the past five years showed an increase of 40 per cent. upon that which prevailed in the preceding quinquenniad; but in the face of its still greater fatality in Birmingham, in which no system of sewerage exists, it is difficult to attribute the increase of diphtheria fatality in London to its main-drainage system. While, as we have noted, the mortality from diphtheria in London has been 40 per cent. greater in the last than in the preceding five years, it showed a decline of nearly 12 per cent. in nineteen of the largest provincial towns, and in Birmingham the decrease was equal to 27 per cent. In studying the nature of diphtheria with a view to its prevention, it may be useful to bear in mind the marked variations in the proportional fatality of the disease in different large towns. Such statistics may assist in the discovery of those conditions which govern the fatality of the disease in different localities. During the ten years 1870-9 the annual death-rate from diphtheria averaged 108 per million persons living in the twenty towns. In the several towns this rate ranged from 33 in Nottingham, 67 in Hull, and 68 in Bristol, to 131 in Sunderland, 182 in Plymouth, and 194 in Birmingham. Thus, during the past ten years, diphtheria has been just six times as fatal in Birmingham as in Nottingham, and the comparative immunity from the disease enjoyed by Nottingham, as well as its excessive fatality in Birmingham, should afford assistance in suggesting means for its control.

SARTORIAL ASPECTS OF THE PUBLIC HEALTH SERVICE.

A VERY serious question is beginning to agitate our public health service and certain sections of the public—namely, whether or not it is desirable that sanitary officers should wear a distinguishing dress. So far as we know, the question has arisen outside the ranks of the service, not within them; and the officers themselves may, we believe, be exonerated from having expressed any desire to be sartorially separated from their fellow-citizens after the manner of the turncock, the policeman, and the parish beadle. The question, in fact, has been raised on public grounds. It is urged, particularly in respect to the inspector of nuisances, that it is expedient he should carry about with him, in the form of a distinguishing dress, to be worn when on duty, obvious indications of his office. Not unfrequently, it is stated, appearing in the habit, as is his custom, of an ordinary individual, his functions and authority are apt to be questioned, and an undue friction created in the performance of his duties, which the wearing of a distinguishing dress would obviate. There is, possibly, something in this, but it may be doubted whether there is not another view of the question which may commend itself more to reasonable people. Probably it would be easy to design badges adapted to the respective dignities of medical officer of health and inspector of nuisances which would stamp them conspicuously whenever and wherever they appeared before the local world, and the dignity which hedges a beadle would thenceforth (if we may venture to bring the less into comparison with the greater) hedge the sanitary officers. But this very dignity, this envious borrowing from beadledom, while, perhaps, fully admissible in the numerous æsthetico-sanitary and other "Orders" which are now multiplying among us, seem to be inconsistent with the educational aim of our present sanitary organization. If sanitary officers work in their districts as they are expected to do, it is surely just as easy to learn to recognise their faces as a peculiarity of their dress, and in the exercise of func-

Digitized by Google

tions which affect the innermost recesses of people's dwellings it appears to us essential to a sound success that the success should be gained by the individual tact of the officer, not by the flaunting of insignia of authority. If sanitary education is to be progressive, beadledom must have no part in it; and sanitary teaching in domestic matters, to be really effective, must be carried out by instructors who are themselves domestic both in habits and dress.

THE BRITON LIFE ASSOCIATION.

THIS office, in which the medical profession has a special interest, has now completed its fourth year as a new undertaking; and it must not be forgotten that, together with its own enterprise proper, it is carrying out the business obligations of the old "Briton, Medical, and General Life Association" much to the advantage of those interested in that closed concern. The annual premium income of the old office in 1869 amounted to £135,621 7*s.* 11*d.* The claims amounted to £145,817 9*s.* 5*d.* The fund in hand at the end of the year stood at £672,121 2*s.* 1*d.* And the commission charged by the new establishment for conducting the business of the old was £8234 17*s.*, or barely more than six per cent. Turning to the junior concern, we find that, notwithstanding the badness of the times, 603 new policies for £176,307 were issued in 1879, producing an additional income of £5664 14*s.* 5*d.* The total income was £21,929 6*s.* 10*d.* The claims falling due in the year amounted to £8409 12*s.* 5*d.* At the close of the year the office had in hand £61,120; a sum stated to equal the total of premium-income received since the formation of the new company for policies in force at the date of the Report. This is evidently a highly satisfactory state of the finances, and may well inspire confidence on the part of assurers. As we remarked last year, with judicious and enterprising management there is every reason to anticipate that the Briton Life Association will not only strengthen its hold on the respect of the profession, but rapidly extend it sphere of usefulness. Its claims are based on a sound commercial policy, fair dealing with the medical men brought into business relations with the office, and a determination to meet the reasonable demands of its clients in the interests of thrift and prudent foresight to the utmost limits of financial expediency and commercial success.

ILL-CONDUCTED INQUESTS.

IT may be hoped that we are now in a fair way of getting an end put to formal inquests, which are delusive to the public, and [as harassing to the friends of the deceased as a real inquiry, and generally more unsatisfactory. A few days ago at the Hammersmith police-court, a bricklayer was committed to trial for manslaughter. The prisoner and the deceased had had a quarrel, described in the *Evening Standard* of the 15th inst. The first blow was given, it is said, by the deceased, who received the next on the left side of his body. As he was falling, the prisoner is stated to have given him a second blow under the right ear, causing him to fall on his side. Dr. Webster, who was called to the deceased, found that he had been dead for some minutes. The remarkable circumstance has now to be noted. The coroner—a medical coroner—did not have a post-mortem examination made. The magistrate expressed, as well he might, his astonishment at this circumstance, and suggested that the police should have power to order a post-mortem. He said he never before heard of one not having been made in such a case. Mr. Pollard, who prosecuted for the Treasury, said there might have been a great failure of justice by the hasty manner in which the coroner conducted the examination. He undertook to convey the magistrate's opinion to Mr. Maule, Q.C., the Public Prosecutor, and Mr. Vincent, the Police Director, between whom perhaps some arrangement might be made. It is very desirable that even yet the exact facts should be ascertained. It is not often that medical coroners are found at fault. But the case before us would appear to be an instance to the contrary effect. And we are sorry to say that it is not singular. We have before us a list of four cases in which a medical coroner acted most inadequately in neglecting to take medical evidence. Amongst lay coroners the formality with which inquests are conducted, and the readiness with which medical and pathological facts are ignored, are simply bringing the whole system into disrepute. Scarcely a week passes in which the most unaccountable deaths happen, and are allowed to pass unelucidated. Post-mortem examinations are inconvenient to most medical men, but they are indispensable in many cases, especially when death happens without any medical attendance.

ROYAL UNIVERSITY OF IRELAND.

ONE of the last acts of the present Government has been to appoint the Chancellor and Senate of the Royal University of Ireland. The Chancellor is his Grace the Duke of Abercorn, and the Senate will consist of thirty-six members, recruited from the ranks of the different professional and lay elements of the community, with, in addition, several members of the nobility. The following are the names of the seven medical gentlemen who have been selected as part of the governing body of the University:—John Thomas Banks, Physician in Ordinary to the Queen in Ireland; Francis Richard Cruise; Thomas Hayden; Robert D. Lyons, M.P. for Dublin; Alexander Macalister, Professor of Anatomy in the University of Dublin; William A. McKeown; and Peter Redfern, Professor of Anatomy and Physiology in the Queen's College, Belfast. We may add, that of the thirty-six senators thirteen have been members of the Senate of the Queen's University, so that the Queen's Colleges are fairly represented on the board of the new institution.

CABUL DISPENSARY.

WE observe with much pleasure that Sir Frederick Roberts has brought to the favourable notice of the Governor-General the meritorious service performed by Dr. C. W. Owen of the Indian Medical Department in establishing at Cabul, and efficiently working, a dispensary for the relief of the sick of the native population of the city and suburbs. It appears from Dr. Owen's report that on the arrival of the force under Sir F. Roberts a temporary dispensary was opened in the rear of the headquarters' camp, but was shortly afterwards transferred to a building in the city, which was quickly fitted up under Dr. Owen's superintendence as a dispensary for out-patients and a hospital with accommodation for 70 to 100 patients. This had not been long in operation when it was found necessary on Dec. 12th to close it on account of the arrival of the enemy. When on Dec. 25th it was again taken possession of, it was found to have been completely wrecked by the insurgents, and everything taken away or destroyed, except the surgical instruments, which were saved by the compounder, a Cabuli, who hid them. Dr. Owen lost no time in getting the hospital into order again, and appears to have worked it with great zeal and success. From Nov. 14th, when the first temporary dispensary was opened in the camp, to Feb. 16th, the date of Dr. Owen's report, there had been 9658 out-patients at the dispensary, and 1305 patients in the hospital. Thirteen major and fifty minor surgical operations had been performed, and eighty-four cases of gunshot wounds, probably received in action with our own troops, were treated. The most numerous cases were eye affections, syphilis of a very severe type, leprosy, scrofula, skin diseases, and round worms. During the severe

Digitized by Google

weather, asthma, bronchitis, and rheumatism were very common; Dr. Owen says that he had never seen such a number of asthmatic cases in his life. It is remarkable that, although scrofula is very prevalent, very few cases of phthisis presented themselves. Small-pox was common, and cases of cancrum oris, leading to the utmost state of misery among the children, were brought in almost daily. Dr. Owen entertains a very unfavourable opinion of the knowledge and skill of the native *hakims*, whose treatment appears to consist chiefly in starving their patients. He was about to deliver a course of lectures on medicine and surgery to them, as several of them had expressed a desire to hear more about Western science. The establishment with which Dr. Owen worked the dispensary consisted of a second-class hospital assistant, a compounder, a dresser, a *bhistie*, a nurse, a cook, two sweepers, and a ward coolie. Dr. Owen is entitled to great credit for his arduous and successful labours "in thus bringing into play the influences of Western medicine and surgery at once in the cause of common humanity, and as an important step towards laying the foundation of a good mutual understanding between the Government, whose servant he is, and the people of Cabul and its vicinity." We trust that the Government will not, as it too often does in the case of medical officers, forget or ignore, in the distribution of rewards, services to which so high a value is attached by the General Commanding the Army in Afghanistan.

THE PATHOLOGY OF HERPES ZOSTER.

SOME of the most interesting examples of the influence of the nervous system upon nutrition-changes are afforded by cutaneous eruptions, and of all these, that of herpes zoster stands out most prominently. The limitation of the herpetic vesicles to the lines of distribution of cutaneous nerves, whether on the limbs or on the trunk, has long led to the opinion that the eruption is neurotic in origin. The earliest anatomical investigations—of necessity few and far between—which went to prove the existence of definite changes in the nerves and ganglia connected with the seat of the cutaneous change are those of Charcot and von Baerensprung, made twenty years ago. Since then other facts have been forthcoming, and the latest contribution to the subject has been made by M. Chandeleux, of Lyons, in the *Archives de Physiologie*. This was a case of zona occurring in the track of the second and third intercostal nerves of the left side in a phthisical subject. The eruption persisted for several months before death. The lungs were extensively diseased and very adherent to the chest-wall, the adhesion being most firm and dense on the left side, opposite to the point of emergence of the second and third intercostal nerves. The subjacent intervertebral ganglia were notably swollen, nodulated, and pigmented. Microscopically these ganglia showed large tracts of sclerosis replacing nerve-cells and fibres, but it was observed that the bundles of nerve-fibres belonging to the anterior roots were healthy. The tissue in the sclerosed parts was disposed in concentrically-arranged bundles, which interlaced with one another, and were surrounded by numerous pigmentary granulations. The outer portions of the sclerosed tracts were infiltrated with small round cells, contrasting with the denser and more organised connective tissue of the central parts. There were but few vessels in the new tissue. The intercostal nerves were hardly, if at all, involved in the morbid change, which is somewhat inexplicable, if the ganglia be considered to be the trophic centres of the posterior nerve-roots. There was no degeneration, or atrophy of nerve-fibres, in the intercostal nerves corresponding to the altered areas in the ganglia, such as might reasonably have been expected to have been found. No changes were found in the main trunk and ganglia of the sympathetic. The cutaneous lesions consisted in bullæ of varying size, some discovered between the Malpighian and corneous layer of the epidermis, others between the epidermis and the dermis itself. The contents of the bullæ were granular serous material, blood-colouring matter, &c. The author publishes the details of this case because of the very marked character of the changes in the intervertebral ganglia.

THE EPSOM COLLEGE CASE.

THE suit brought against the Head Master and Medical Officer of Epsom College was not successful. The jury did not consider that any breach of trust had been committed, or wrong done to the plaintiff or the youth who so unhappily died in the infirmary of the college wherein he was a boarder. Every one will sympathise with Dr. Howell, and yet, perhaps, no one will regret to find that this school has escaped a judgment which would have been most injurious, if not ruinous, to its reputation. The contention on behalf of the school authorities was, that the deceased had been treated as a member of the family of the head master, who would have sent his own son into the same apartment, and treated him precisely as Dr. Howell's son was treated. This contention seems to have been maintained. In future it would be wise to make clear to the parents of boarders that, in the event of illness involving the possibility of epidemic disease occurring to their children, they must be removed to the wards set apart for general purposes. At the same time, every precaution ought to be taken to insure that these wards shall be kept in a condition to receive sick inmates on an emergency, and that the system of nursing and general care of such patients shall be of a nature to satisfy not only the requirements of health in the college, but those natural solicitudes which must possess the mind of every parent, and all humane persons must understand and approve. There is no need to extend the notice of this sad case, still less does it call for critical remark.

HEALTH AND MORTALITY IN PAUPER SCHOOLS.

ON Tuesday last Dr. Mouat, one of the medical inspectors of the Local Government Board, read at the Statistical Society a paper on the "Education and Training of the Children of the Poor." The paper was a valuable contribution to a subject, the importance of which, from a social point of view, cannot be over-estimated, more especially when we bear in mind that between 30,000 and 40,000 children in England and Wales are constantly under the control of the guardians of the poor, in workhouses, in separate or district schools, or in similar institutions. The political and economic aspects of the question, full of interest as they are, it is out of our province to discuss, and we must express our disappointment at the small proportion of Dr. Mouat's paper devoted to the hygienic treatment, and to the health and disease statistics relating to this large number of pauper children. We have often noted the remissness of the Local Government Board in not supplying in their annual reports trustworthy statistics of health and disease of the children in the various workhouse establishments. The opportunities for daily physical and hygienic observation and deduction afforded by these institutions are wantonly thrown away for want of a simple and intelligent system of returns, which would involve far less tax upon the officials than many other returns of doubtful value they are now called upon to make. Data for calculating even the rates of mortality in pauper schools are wanting. In this respect the Metropolitan Asylums Board is considerably in advance of the Local Government Board, as they publish in their fortnightly minutes returns showing number of residents, admissions, deaths, and discharges in

Digitized by Google

each of the institutions under their control. Dr. Mouat states that Dr. Bridges calculated the rate of mortality in the metropolitan workhouse schools in 1873 to be 12 per 1000. We published about a year since a careful analysis of the mortality in these metropolitan schools during the three years 1875–6–7, which showed the average annual rate to be 12·8 per 1000; this differs little from Dr. Bridges' calculated rate for 1873. When, however, Dr. Mouat states that the death-rate among children in the metropolis aged two to fifteen years is 1·1 per 1000, it is evident he is misinformed. The annual rate at these ages has only ranged from 10 to 12 per 1000 in recent years, and in our analysis of the mortality in these schools, to which we have referred, we pointed out that having due regard to the age-constitution of their population, the normal or life-table death-rate for these schools is only 8·1 per 1000. The mortality in these schools, therefore, exceeds the normal rate by 50 per cent. As a matter of fact, these schools contain very few children aged under three years, and the death-rate at ages from 3—15 years in London in recent years has averaged only 8 per 1000. How much of this excess is due to the low physical stamina of the pauper children, and how much to injudicious hygienic treatment in the schools, cannot be determined without careful and uniform observations. It should not be forgotten, however, that the mortality statistics of sixteen metropolitan pauper schools showed wide variations, which should point to the necessity for further information on the subject. The rate of mortality during the three years averaged only 4·5 in the North Surrey, 6·9 in the Bethnal-green, and 7·5 in the South Metropolitan Schools, whereas it averaged upwards of 13·6 in the Holborn, 19·6 in the Forest-gate, and 42·4 in the Marylebone Schools.

THE REPRESENTATION OF THE SCOTCH UNIVERSITIES.

THE result of the elections in the Scotch Universities leaves the position of political parties unchanged, and it does not add another medical man to the House. We should have been glad to see Mr. Bickersteth in Parliament, but it would have been a misfortune had Dr. Lyon Playfair been excluded. He is not a medical man, it is true. But he is next door to being one, and has made himself so useful in connexion with educational and scientific subjects, and as a member of the Select Committee on Medical Bills, that we rejoice to see him again in the House. He will abundantly justify his friends in their support of his candidature if he helps to adjust the differences between medical reformers in the Scotch Universities, who seem to see lions in the way, and other medical reformers who see none.

TRAINING SHIPS.

WE have a double interest in the fate of the *Atalanta*—the old *Juno*. First, two members of our profession are among the missing crew; and, second, in the cause of humanity it is time to protest against the mistaken policy of sending out special ships crowded with young seamen, for the purpose of training, on exceptional voyages. The fact of any particular vessel being told off for this duty would place it in peculiar risk. When a craft is sent to sea with no other object than to cruise about and exercise those on board, sailing and ship-handling come to be the principal if not the sole objects in view; and in proportion as those in command are enterprising, will every advantage be taken of the circumstances to show "seamanship." It is needless to affirm that the perils likely to be encountered on any ordinary expedition with a legitimate purpose are sure to be less than those which would be run on a voyage like that in which the *Eurydice* was lost, or that in the course of which the *Atalanta* is now missing. It is impossible not to feel that the practice of sending vessels full of youths to sea is bad, however well the ship may be provided with a crew of able seamen. It is far better to let the boys of the Navy get their seamanship on ordinary duty. If there are no ships on the stations or in the fleet wherein they can learn to be sailors, so much the worse for our Navy, unless indeed seamanship as an art is obsolete. If this be the case, why run a needless risk in training? Again, we protest against the employment of ships of the old "Surveyor's" class on this or any other service. They were well known to roll dangerously—in fact like casks on the water; so that nothing but a feeling of indifference as to which side of the cask might happen to lie uppermost could relieve the anxiety of the onlooker. The matter is a very serious one, and requires to be rigorously re-viewed.

PARASITES IN TYPHOID FEVER.

DR. BUCHANAN'S paper containing an account of Mr. W. H. Power's observations on the voluntary muscles in typhoid fever, which will be found in our report of the last meeting of the Pathological Society, will be read with considerable interest and curiosity. Mr. Power believes that he has found certain nematoid parasites somewhat resembling, but quite distinct from, the Trichina spiralis in some of the voluntary muscles, especially the pectoralis major and psoas. If the observations are correct, they are of very great importance and interest, but at present even the least sceptical must withhold any definite opinion on the subject. For first of all Mr. Power's investigations have extended to only two subjects, and his paper may, therefore, be thought to be a little premature. He also describes certain other smaller bodies which he believes may have some relation to the parasites, but which are so evanescent that even a slight interference with the slide will often cause their entire disappearance. When we add that the supposed parasites are especially met with when decomposition has begun its destructive work; and that pathologists have for years been in the constant habit of examining microscopically the voluntary muscles in typhoid fever, and have described degeneration of the fibres, but have not hitherto met with any appearances suggestive of parasites, it will be evident that Mr. Power's statements must, in their more general bearing, be still held to require confirmation.

SIR THOMAS NELSON.

IN a recent annotation, entitled "Unacknowledged Services," we drew attention to the claims of the City Solicitor to some honourable recognition of his great services to the cause of public health and the interests and enjoyment of the people of London by the preservation of open spaces around London, notably Epping Forest, in the freeing of the bridges, and in other undertakings of public value—for example, the defence and improvement of endowed schools. It is gratifying to find that our remarks have not been wholly inoperative. Mr. Nelson has been knighted; and looking back on the matter, we are now very glad that the honour has not been conferred upon him—as a lay figure might be decorated—for the glorification of the City of London, but in direct acknowledgment of his personal worth and work.

STEREOSCOPIC MICROSCOPY.

AT the close of the meeting of the Pathological Society on Tuesday last, Dr. Heneage Gibbes gave a very interesting demonstration, showing how it is possible to get with one-twelfth oil immersion a stereoscopic effect with the ordinary binocular microscope, both fields being perfectly illuminated. The interest will be appreciated when it is added, that by this means epithelial cells were not seen as flat scales, but as spheres, standing out in all their rotundity, and that the precise relations of cells and fibres, layer by

Digitized by Google

layer, could be thoroughly appreciated. This of course gives a much more accurate impression of the structure under examination than can be obtained by the ordinary method of examination. The specimen used for the demonstration was also of considerable interest, as it well and clearly showed dividing epithelium in the skin of the embryo salamander.

THE CIRCLES OF MEDICAL ADMINISTRATION IN INDIA.

THE *Gazette of India* of the 20th March publishes the names of the officers appointed to the new circles of medical administration in the Bengal Presidency; British Medical Service:—Deputy Surgeon-Generals J. Gibbons, C.B., to the Allahabad Division; E. J. Franklyn, to the Meerut Division; J. E. Clutterbuck, to the Oudh Division; A. Smith, C.B., to the Rawal Pindi Division; H. B. Hassard, to the Sirhind Division; H. Fraser, to the Peshawur Division. Indian Medical Service: Deputy Surgeon-Generals W. B. Beatson, to the Lahore Division; J. J. Clarke, to the Eastern Frontier District; J. E. Tuson, to the Presidency Division; R. H. Perkins, to the Gwalior District; A. C. H. De Renzy, to the Punjab Frontier District. These officers are ordered to join by the 1st April, 1880, proceeding to their stations with the least possible delay.

THE HEALTH OF ST. PETERSBURG.

DR. HUBNER'S report on the mortality of St. Petersburg in 1879 shews that the health-conditions of the city were more favourable in that year than in the years 1877 and 1878. The mortality from all causes during 1879 was at the rate of 39·0 per 1000 inhabitants, but in the two previous years it had been at the rate of no less than 46·0 per 1000. Under ordinary conditions the deaths from small-pox in the capital number about 100 annually, but in the past year they amounted to 1180. This, although unsatisfactory, is much less than the mortality caused by the epidemic of 1872–73, which carried off 4000 persons. In the course of the year, moreover, true typhus showed itself, especially among the labouring classes, who are too commonly ill-housed and "packed like herrings," as Dr. Hübner says, in single chambers, hence great overcrowding. Numerous labourers flocking into the city from the country in search of work, and failing in the search, augment the numbers of the poverty-stricken and sick.

The mortality return for the city (population 670,600) during the week ending 27th March, records 726 deaths (456 males and 267 females) from all causes. Typhus and typhoid fevers caused 16·0 per cent. of the mortality (62 deaths being assigned to maculated typhus).

LEPROSY AND THE USE OF GURJUN OIL.

THE report of the medical officer (Mr. John D. Hillis) of the Leper Asylum, Mahaica, British Guiana, for the year 1879, is chiefly interesting for the information it affords of the improved local conditions under which the lepers in that asylum are now placed, and the observations it contains on the use of gurjun oil in the treatment of leprosy. It appears that Dr. Gavin Milroy visited the asylum in 1871, and condemned the site on which it was placed, and generally the buildings, advocating their abandonment. Since then it would appear, that by the reclamation of malarious ground to the windward of the asylum, and judicious improvements of and additions to the buildings, considerable amendments have been made, and the general condemnation of Dr. Milroy no longer applies.

With regard to the use of gurjun oil, Mr. Hillis reports that "even in cases far advanced it is most beneficial, retarding the disease in a remarkable manner, and improving the general health." He is of opinion that it should be in general use in every leper asylum, and adds, "It is largely sought after by the patients, notwithstanding its unpleasantness, on account of its healing action on the leprous ulcerations and its appetite-giving properties." He quotes a series of cases in which he has made use of the oil, and thinks that if it were possible for cases to be brought under treatment in an early stage, on the first appearance of the leper spot, before the deposit of leprous matter had become serious, an attack, if not cut short, might at least be retarded in progress for many years by the administration of the oil.

SURGEON-MAJOR SIR SAMUEL ROWE, K.C.M.G.

WE are very glad to note in the recent distribution of honours that the services of a medical officer have not been overlooked. The *Gazette* of Wednesday announces the promotion of Surgeon-Major Samuel Rowe, C.M.G., to be Knight Commander of the Most Distinguished Order of Saint Michael and Saint George. Dr. Rowe, who has been for many years in the African Medical Service, did good service in the Ashantee Campaign under Sir Garnet Wolseley, and on the termination of the war was employed by the Colonial Office as Governor and Commander-in-Chief of the West African Settlements, which office he still holds.

WILLIAM SHARPEY, M.D., F.R.S.

IN another column we have noticed at length the more interesting features and episodes of the life of the late Dr. Sharpey. Suffice it, in this place, to record the regret with which his decease will be felt by the profession at large, and particularly by those who cherish the memories that cluster round a name which helps to mark off an epoch.

THE SUCCESSOR TO DR. FARR, C.B.

DR. WILLIAM OGLE, F.R.C.P., has been appointed Superintendent of Statistics in the Registrar-General's Department, in the room of Dr. William Farr, resigned.

A GOOD EXAMPLE.

WE are glad to learn that the Council of the Royal College of Surgeons in Ireland has passed a resolution to the effect that the practice of indirectly advertising through the medium of sensation articles in the general press, being beneath the dignity of the profession, is deserving of repudiation and condemnation.

A SAD accident, which, unhappily, appears likely to have a fatal issue, is reported in the *New York Times* of April 6th as having happened to Dr. C. H. H. Sayre, son of Dr. Lewis A. Sayre. The unfortunate gentleman seems, in turning round rapidly, to have missed his footing and to have fallen a depth of twenty feet, down an area in front of the Gilsey House Hotel, sustaining thereby, besides other injuries, a compound comminuted fracture of the thigh. Dr. Lewis Sayre was speedily in attendance on his son, and undertook the operation rendered necessary by the aggravated character of the injury. The ends of the broken bone were sawn off, three fragments removed, and the limb placed in position, a plaster-of-Paris bandage being employed. The sufferer is twenty-seven years of age.

A LETTER from the Local Government Board having been read at a late meeting of the Jarrow Town Council, asking what steps were being taken in conjunction with the local authorities at Hebburn towards the erection of a hospital for infectious diseases, the clerk was instructed to reply that the matter was in abeyance owing to the refusal of the Hebburn authorities to join with Jarrow in the project.

THE first of the Shepherd Memorial Gold Medals, one of which is to be presented yearly to a student of medicine of Aberdeen University who shall have completed his third year of study, and exhibited the greatest proficiency in the principles and practice of surgery, has, after examination both written and oral, been awarded to Mr. Duncan J. Reid, of Aberdeen. The examination was conducted at Marischal College by Professor Pirrie, in presence of Dr. David Greig as assessor.

IT is announced that the Port of London Sanitary Authority are about to issue advertisements inviting candidates for the post of medical officer of health for the port, vacant by the death of Mr. Harry Leach. In accordance with an instruction of the Court of Common Council, five candidates are to be chosen, whose names are to be submitted to the Court, with whom will rest the particular selection for the office. Candidates over forty-five years of age are inadmissible.

BRIGADIER-GENERAL J. L. NATION, commanding Naga Expeditionary Force, in a despatch to the Governor-General of India in Council, writes :—"To the medical staff, Deputy Surgeon-General De Renzy, Surgeons O'Brien and Campbell, my best thanks are due, as they frequently had to perform their errand of mercy under heavy fire, and their arduous duties were most nobly and ably performed."

Apropos of communications which have appeared from time to time in our pages respecting typhoid in India, it may be well to draw attention to the paper to be read by Surgeon-General Gordon on Thursday next at a special meeting of the Epidemiological Society, to be held in the Council-room of University College at 8 P.M.

AN election for a Member of Council took place on the 15th inst., at the Royal College of Surgeons in Ireland, for the vacancy caused by the resignation of Prof. MacDowell, recently appointed examiner. Messrs. Corley and Nixon were the two candidates, the former being successful, having obtained 42 out of 71 votes recorded.

DR. G. WATERS, Surgeon Bombay Medical Service, has been appointed surgeon on the staff of Sir James Fergusson, the new Governor of the Bombay Presidency. Dr. Waters has for some years filled a similar position as medical officer to Sir Richard Temple, Bart., G.C.S.I.

PROFESSOR VIRCHOW was, on the 14th inst., returned to the German Imperial Parliament for the second electoral district of the capital as the candidate of the United Liberals, he himself voting in the Prussian Chamber as a Progressist.

THE twentieth festival of the Royal Medical Benevolent College will be held at the Langham Hotel on Wednesday, April 28th. Sir William Jenner, Bart., has consented to preside on the occasion.

BRIGADE SURGEON J. HANNAN has been appointed to officiate as Deputy Surgeon-General, Sirhind Division, during the absence of Deputy Surgeon-General H. B. Hassard, employed with the Cabul field force in Afghanistan.

BRIGADE-SURGEON F. W. MOORE has been nominated Deputy Surgeon-General of the Rawal Pindi Division, vice Deputy Surgeon-General A. Smith, C.B., on duty with the Kandahar army in Afghanistan.

THE medical committee formed to secure the return of Dr. Lyons for Dublin propose entertaining him at dinner on Saturday (this evening), at the Shelbourne Hotel in that city.

A MOTION by Professor Struthers, that it is desirable that a Professorship of Pathological Anatomy be established in the University of Aberdeen, has been unanimously adopted by the University Council.

DR. CHARTERIS has, we understand, been appointed to the chair of Materia Medica in the University of Glasgow, in the room of Dr. Cowan, resigned.

BRIGADE-SURGEON TARRANT has been appointed to officiate as Principal Medical Officer of the Northern District of York.

THE death is announced of Dr. Francesco Marzolo, Professor of Clinical Surgery in the University of Padua.

A NEW Dental Hospital was opened on the 15th inst., at Liverpool.

HEALTH OF LARGE ENGLISH TOWNS.

FIFTEENTH WEEK OF 1880.

URBAN mortality last week differed but slightly from that which prevailed in the previous week. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5458 births and 3267 deaths were registered last week. The births exceeded by 273, while the deaths were 8 below, the average weekly numbers during 1879. The deaths exceeded those returned in the previous week by 23, and were equal to an annual rate of 22·7 per 1000 of the estimated population, against 24·9 and 22·5 in the two preceding weeks. During the thirteen weeks of last quarter the death-rate in these towns averaged 25·5 per 1000 against 25·2 and 27·5 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 16·3 in Portsmouth, 16·5 in Leeds, 19·5 in Hull, and 19·6 in Bristol. The rates in the other towns ranged upwards to 27·6 in Oldham, 27·7 in Liverpool, 28·5 in Nottingham, 28·6 in Newcastle-upon-Tyne and Norwich, and again the highest rate, 29·9, in the borough of Plymouth. The excessive rate in Plymouth is still mainly due to the exceptionally fatal epidemic of measles, which shows no sign of abatement.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 531 and 449 in the two preceding weeks, further declined to 445 last week. They included 167 from whooping-cough, 107 from scarlet fever, 89 from measles, and 33 from fever, principally enteric. The annual death-rate from these seven diseases averaged 3·1 per 1000 in the twenty towns, and ranged from 0·5 and 1·1 in Brighton and Leeds, to 4·5 in Nottingham and Newcastle-upon-Tyne, 5·5 in Norwich, and 14·6 in Plymouth. Whooping-cough showed the largest proportional fatality in Newcastle-upon-Tyne, Manchester, and Salford; scarlet fever in Norwich, Newcastle-upon-Tyne, Leicester, and Sunderland; and measles in Plymouth, Nottingham, Hull, and Oldham. Measles caused 17 more deaths in Plymouth, making 213 recorded within that borough since the early part of November last. Eight of the 13 fatal cases of diphtheria were returned in London; and 4 more deaths were referred to enteric fever in Sheffield, making 74 since the beginning of the year. All the 9 fatal cases of small-pox in the twenty towns were recorded in London. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 167, 172, and 177 at the end of the three preceding weeks, further rose to 178 on Saturday last; 44 new cases of small-pox were admitted to those hospitals during last week, against 47 and 42 in the two previous weeks. The Highgate Small-pox Hospital contained 22 patients on Saturday last, a larger number than at any time since July, 1878.

The fatality of lung diseases in our large English towns showed a further decline last week. The deaths referred to diseases of the respiratory organs in London, which had been 395 and 365 in the two previous weeks, further declined to 348 last week, and were 58 below the corrected weekly average; 218 resulted from bronchitis, and 78 from pneu-

Digitized by Google

monia. The annual death-rate from diseases of this class was equal to 5·0 per 1000 in London last week; in Liverpool the rate from the same diseases was 6·3 per 1000.

THE BRITON LIFE ASSOCIATION.

THE annual meeting of the proprietors of the Briton Life Association, Limited, was held on Tuesday in the board-room at the chief office, Strand, London, under the presidency of Mr. Francis Webb, and there was, as usual, a large attendance.

Mr. John Messent, the actuary and secretary, having read the notice calling the meeting, presented the report of accounts. From the report we gather that during the past year the Association received 810 proposals for assuring the sum of £261,483. Of these 23 for £7770 were declined; 184 for £77,405 were incomplete at the time of closing the books; and 603 policies were issued, assuring the sum of £176,307, and yielding in new annual premiums the sum of £5664. The single premiums received in respect of annuities granted by the Association amounted to £150, making a total of £5814, as the new business of the year. The receipts from premiums for the year, less the sum paid for re-assurance, amounted to £17,743; the interest to £2814; the fines and fees, £10; the profit from investments, £1361; making the total year's income £21,929. The claims for the year have been exceptionally heavy. Not only has the Society suffered, in common with other assurance companies, by the unexampled severity of the past season, but it has lost from purely accidental causes some of its most recently joined and heavily assured members. The number of policies which have become claims in the year is 24 for £8409 12*s.* 5*d.*; but a careful review of each particular case shows that the unusually heavy mortality exhibited by these figures can only be regarded as one of those contingencies against which all assurance companies are established to provide, and as affording powerful and practical evidence of the inestimable advantages to be derived by the public from an adoption of the principles of life assurance.

The CHAIRMAN said he thought he might very fairly congratulate the meeting upon the results of the operations of the Association during the year under review. Notwithstanding the great depression in trade and commerce generally, thanks to the energy of its agents and staff, the accounts showed that the Association had not only been able to hold its own, but also to show a fair and, under the circumstances, a very remarkable progress in regard to the new business done. It was well known that when trade was brisk money freely circulated, and people receiving it thought they ought to make some provision for the future; but when times were bad and money scarce then people did not care so much for the future as to maintain themselves in the present, and then life assurance suffered generally. They had, however, no reason to be discouraged with the report presented to-day, for in every important item as regarded the Company's stability there was an important advance. Truly the total aggregate of claims had been heavy for a comparatively young company, but it arose from exceptional circumstances, one being that of a gentleman who had insured with the Company, and within six months of doing so was unfortunately accidentally caught by machinery on his own premises and killed. In other respects the claims were rather below the expectancy of the office, thus showing that the lives had been selected with the usual judgment and care. The assets, both active and passive, yielded 4¼ per cent. interest. The total premium income was greater by £2132 than that of the previous year, and the available assets in hand were equal to the total amount the Association had received since its formation. In conclusion he said that the Association had the three great elements of success—an increased premium income, a decrease in its working expenses, and an increase in the interest on its investments. He moved that the report and accounts be received and adopted.

Dr. RICHARDS, the Deputy-Chairman, seconded the motion, which was adopted, *nem. con.*, without discussion.

The retiring directors were unanimously re-elected.

The appointment of Mr. R. Monckton, Colonel Harington, A. Trevelyan, and Mr. R. Milburn to seats at the board was confirmed, and unanimous votes of thanks having been accorded to the medical and legal officers, to Mr. Messent, the actuary, and the agents and staff, the proceedings closed with a vote of thanks to the chairman.

A meeting of the shareholders in the Briton, Medical and General Life Association was subsequently held under the presidency of Mr. Francis Webb.

Mr. JOHN MESSENT, the actuary and secretary, read the notice calling the meeting, and presented the report and accounts. The report said that the premium income of the year, after deducting re-assurance premiums, amounted to £135,621, the interest (less income tax) to £28,787, miscellaneous items £10, making a total year's income of £164,418. The claims had been 458 in number by reason of the debts of 405 assured lives, and have amounted, less re-assurances, to the sum of £145,817. The total expenditure of the Association, including agents' commission, amounts to the sum of £8234, or £6 per cent. on the premium; the funds in hand—i.e., the balance of assets over liabilities—amount to the sum of £672,121.

The CHAIRMAN, in moving the adoption of the report and accounts, expressed his belief in the sound position of the Society. He also pointed out that the rate of interest had been well maintained, and said that though the funds were somewhat less than was anticipated, it was due to the fact that there had been some exceptionally heavy claims; they were more than when the Society was placed on its present footing in 1875. The actuarial valuation was in progress, and he believed that when the results were made known they would be satisfactory to all concerned.

The motion having been seconded, was unanimously agreed to.

The usual routine business having been transacted, the proceedings closed with a hearty vote of thanks to the chairman, his colleagues, and the actuary.

Correspondence.

"Audi alteram partem."

RELIGIOUS LIBERTY IN TURKEY AND IN ENGLAND: A CONTRAST.

To the Editor of THE LANCET.

SIR,—The following paragraph appeared in the *Times*, April 16th, 1880:—"The Sublime Porte having expressed its desire to maintain to the utmost extent the principles of religious liberty, the high contracting Powers take note of its spontaneous declaration. *In no part of the Ottoman Empire shall difference of religion be held in the case of any person as a motive for exclusion from or disqualification for any public function, nor from the advantages of the exercise of any profession of industry.*"

The following correspondence lately passed between an intending candidate for the post of Professor of Ophthalmology at, and the Secretary of, King's College.

Comment is unnecessary. Faithfully yours,

J. B. B.

SIR,—I find one of the conditions of candidature for the posts of Professor of Ophthalmology of King's College and Ophthalmic Surgeon of King's College Hospital to be that "all candidates must be members of the United Church of England and Ireland, and must make a declaration to that effect in their application."

As I should be unable to make such a declaration, I shall esteem it a favour if you will be so good as to inform me whether I should thereby be disqualified as a candidate for these posts. I am, Sir, yours truly,

J. W. Cunningham, Esq. JOHN TWEEDY.

DEAR SIR,—I am sorry to tell you that the Council would have no power to elect you, provided you are not a member of the Church of England. Their Charter is decisive upon the subject in all cases except teachers of foreign languages.

I am, very truly yours,

King's College, London, 28th Jan., 1880. W. CUNNINGHAM.

THE CROTON-OIL TREATMENT OF RINGWORM.

To the Editor of THE LANCET.

SIR,—May I ask you kindly to publish this final reply to Mr. Cottle's letter in THE LANCET of April 17th. I thought my communication of the 10th inst. would have been sufficient. But as he still claims priority in bringing before the notice of the profession the croton-oil treatment of chronic ringworm, described in my paper in the January numbers of THE LANCET, I must, in justice to myself, say that the *artificial production of kerion* was the course I advocated; and as Mr. Cottle still affirms that a pustular rash is sufficient, and that the production of kerion is unnecessary, the matter is settled. I advised as *my* special treatment what he does not consider necessary.

I do not for one moment suppose I was the first to use croton oil for ringworm, or that Mr. Cottle was; but this I do assert, that I have been producing kerion with excellent results in inveterate ringworm during the last six years, having notes of cases which occurred in 1875. I did verbally bring my treatment under the notice of the profession three years ago, in a long conversation on the subject with the late Dr. Tilbury Fox. I also mentioned it in 1878 to Dr. Liveing, and other dermatologists; and can prove that my paper has actually been written eighteen months. My reason for not publishing it sooner was to give the croton-oil treatment a trial during another year, as well as the oleate of mercury.

I remain, Sir, yours obediently,

ALDER SMITH, M.B. LOND., F.R.C.S.
Resident Medical Officer, Christ's Hospital.

April 19th, 1880.

P.S.—Will you allow me also to correct a mistake which is now prevalent—viz., that we have a number of ringworm cases at Christ's Hospital. Such is not the case. Our usual number is from ½ to 1 per cent., while the percentage among boys brought to us for admission is 8·4.

PATHOLOGY OF SPIRILLUM FEVER.

To the Editor of THE LANCET.

Sir,—Adverting to the discussion at the Medico-Chirurgical Society, on my communication, as reported in THE LANCET of 28th February, all I can say is that when they left me the microscopical preparations of the blood-spirillum were all clear, and two or three were even exquisite examples of the state of the blood in infected quadrumana.

I beg leave to observe that there is no possibility of an experienced eye mistaking the blood parasite for a common fungus.

To the best of my knowledge this organism is found only in famine or relapsing fever, pure or complicated. Its relationship to the pyrexia may not be immediate or direct, but within my experience spirillar infection of the blood has always culminated in a febrile attack.

I would here add that I have lately succeeded in inducing spirillum fever amongst the quadrumana by inoculating with infected blood taken during the prefebrile incubation period. This fact modifies one of my earlier conclusions.

I am, Sir, your obedient servant,

March 20th, 1880. H. V. CARTER.

Obituary.

WILLIAM SHARPEY, M.D., LL.D., F.R.S.

WILLIAM SHARPEY was born at Arbroath on April 1st, 1802, his father, an Englishman who had migrated from Folkestone to Arbroath, having died shortly before. For the first few hours after his birth his life was despaired of, and in after days he would humorously relate how the midwife, in the midst of the efforts made to insure his living, expressed in strong native accents, her opinion of the undesirability of these endeavours, since if the child lived it would be sure to prove an idiot. He learned the rudiments of the medical profession under Dr. Arrott of Arbroath, who had married his mother, and in 1817 entered the University of Edinburgh, joining the medical classes in the following year. In 1821 he gained the diploma of the Royal College of Surgeons of Edinburgh, and in 1822 he came to London, wherefor some time he studied Anatomy in the school of the celebrated Brooks, in Windmill-street. The following winter he spent in Paris, and returning afterwards to Edinburgh, graduated in 1823, the subject of his thesis for the doctorate being "Cancer of the Stomach."

A part of the next few years of his life seems to have been spent at Arbroath in private practice under his stepfather, Dr. Arrott, but his call in life at last came to him, and in 1827 he set out for the Continent, with the view partly of general culture, and partly of training himself for his future scientific career. He travelled through a large part of Germany, Switzerland, and Italy, performing his journeys for the most part on foot, bearing his knapsack, talking freely with the people among whom he passed, and gathering up that large fund of knowledge of men, places, and things which was one of the many striking features of his character. Part of the time spent abroad was, however, devoted to arduous scientific study. At Pavia under Panizza, and more especially at Berlin under Rudolphi, he dissected with great diligence, and made himself master of topographical Anatomy. The writer has often heard him speak of his time at Berlin as one of sustained and severe labour. It was undoubtedly there that he especially trained himself for his future career. He also passed some time in study at Paris, at Heidelberg under Tiedemann, and at Vienna. In 1829 he had returned to Edinburgh. In 1829 he became Fellow of the Edinburgh College of Surgeons, on which occasion he published an Inaugural Dissertation on the "Formation of False Joints after Resection." He also wrote at this time his first paper on "A Peculiar Motion in Animals, &c.," published in the *Edinburgh Medical and Surgical Journal*, the researches described in which formed the basis of the well-known and able article "Cilia," which some years later appeared in Todd's Cyclopædia of Anatomy and Physiology.

In the autumn of 1831 he spent some time in Berlin, preparatory to beginning the teaching of Anatomy. This work he commenced in November of the same year as lecturer in the Extra-Academical School at Edinburgh, having his friend Allen Thomson for a colleague as lecturer on Physiology. He continued this labour until 1836, when he was appointed successor to Jones Quain in the chair of Anatomy and Physiology in what is now known as University College, London. This post he held for nearly forty years, not leaving it until 1874, when the increasing infirmities of old age compelled his retirement. In 1855 he was appointed one of the Secretaries of the Royal Society, of which he had been made a Fellow in 1839, and the duties of this office also he resigned in 1874. The Baly medal of this Society was conferred upon him for Physiological research. In 1859 he was honoured with the degree of LL.D. by his own University of Edinburgh. He was long associated with the University of London, first as Examiner in Anatomy and Physiology, an office which he held more than once, and afterwards as Member of the Senate. He took an active part in the Royal Commission on Science appointed in 1870. He was also a trustee of the Hunterian Museum, and sat for fifteen years in the General Medical Council as one of the Crown nominees. The Government recognised the long services of Dr. Sharpey by awarding him a pension of £150 a year.

But a few years ago William Sharpey seemed a hale and hearty man, and his massive frame, in spite of increasing age, showed a vigour which seemed to promise still many years of usefulness. The onset of cataract first in one eye and then in the other, marked the first stages of his decay. The imperfection in his sight, together with some dulness in hearing, rendering him who had always been so self-reliant more or less dependent on others, and thus interfering with the freedom of his movements, had a very markedly depressing effect on him. In the spring of 1879, a severe attack of bronchitis, with alarming hæmorrhage, shook his constitution still further, and it was evident to his friends that he was gradually becoming more feeble. The greater part of last winter was spent in the mild air of Hastings, where he

Digitized by Google

gained the double benefit of escaping the fogs of London and enjoying the society and conversation of his learned and accomplished friend Dr. Greenhill. On his return to the metropolis last month he appeared to be decidedly in better health. He had, however, returned too soon, and was, perhaps, not sufficiently careful to avoid exposing himself, for on the 1st of April he was seized with a sharp feverish attack of bronchitis, which excited alarm in the minds of his friends, and from which he himself despaired of recovering. On the 9th and 10th of the present month the fever had left him, and Mr. Marshall and Dr. Ringer, who attended him, entertained some hopes that he might recover. But on the morning of the 11th he exhausted himself by going through the process of dressing, and collapse having come on in the forenoon of that day, his powers rapidly failed, and he died most peacefully in his chair before eleven o'clock at night.

When we look back upon Dr. Sharpey's long life, we see that it had a threefold character. He was a scientific investigator, a public man of science, and a teacher. The first form of activity occupied chiefly his earlier days at Edinburgh; his middle life and later years were more especially devoted to the two latter. In all three he was eminently successful, and in each case success was achieved by dint of the same mental qualities. He was remarkable for his power of clear and sound judgment. He was also distinguished for the great amount of knowledge which he had accumulated—knowledge as accurate as it was varied. Not in matters of anatomy and physiology alone, but in reference to many other subjects, he could call up at will a long array of data in the form, not of uncertain and confused impressions and remembrances, but of clear and sharply-defined statements, the products of accurate painstaking observation preserved by means of a memory naturally retentive and carefully trained. On the other hand, the judicial attitude of his mind compelled him to keep the treasures of his memory marshalled in orderly array, available for instant and decisive use. Had he been lacking in critical power, his stores of knowledge were enough to have made him distinguished for his learning; had he been as ignorant as he was learned, his faculty of weighing in the balance and of finding out the weightier argument would still have left him a strong man. The happy union of large knowledge with clear judgment made him, or rather went far to make him, the remarkable man that he was. These qualities served him in good stead in his public services as Secretary of the Royal Society and in other offices. At a glance he would recognise the merits of a memoir, and with equal readiness he perceived and acknowledged the merits of a research which by a less competent judge might have been opposed on account of the apparent heresy of the results or neglected on account of the modesty or obscurity of the author. Two things his soul abhorred: the smartness which tries to produce something novel and startling out of crude and hasty observations, and the ambitious dulness which would fain have the public believe that something precious is contained in its lengthy and pretentious dissertations; and English scientific literature has been saved from many inflictions of both kinds by the attitude of William Sharpey. The same qualities helped to make him a great teacher. When he was in his vigour all the facts of anatomy and physiology were at his finger ends. He knew not only what many teachers are satisfied to know, the contents of the last few volumes of the scientific journals, but very much besides. He knew the old as well as the new, and was as much at home with Vesalius and Haller as with Bernard and Ludwig. His exposition of any subject was ever clear and lucid, because he knew the thing for himself, and had thought it carefully out, never being content with conning it over "for lecture purposes." It was impossible for him to be otherwise than clear, for his mind refused to harbour obscurities, and the simple secret of his teaching was that he laid open his own mind to his pupils. If there were any subject which he did not understand he candidly said so, and those who heard him knew that that subject might fairly be postponed; in all other matters his method was to lay before his hearers in plain straightforward language just how the thing appeared to him, describing the facts with scrupulous accuracy, putting down the arguments as they were arrayed before himself, and leaving on the students an impress, sometimes strong, sometimes feeble, according to the nature of the material, or the working of his own mind. In this way it came to pass that his hearers, often unbeknown to themselves, not only acquired that superficial knowledge of physiological facts and doctrines which will pass muster at an examination, and serve other similar subsidiary purposes; but also acquired the art of physiological reasoning, and caught some of the true spirit of physiological judgment. Thus it is that many of his pupils, whether engaged as medical practitioners, or following other occupations, have been enabled to arrive at sound conclusions for themselves on questions which have come up since, and have not been tossed about by every wind of false doctrine.

The same qualities are visible in his original work, and are at the same time in part the reason why his labours as an investigator seem so comparatively scanty. An exact quantitative estimation of Sharpey's work is perhaps impossible; so much of it is hidden and mixed with that of others in various publications, such as Baly's translation of Müller's Physiology, Quain's Anatomy, and the like. Whatever he did was, however, done in such a way that very little had to be undone. Every bit of work which left his hand bore the stamp of that exact large knowledge and sound judgment which we have already indicated. Small as his acknowledged contributions to science may be when judged by the number of pages, small as they still may be considered even when we include results not published in his own name, they are classical efforts which will not readily be forgotten. Had he never been a great teacher or a successful public man, his name would still be honoured as that of an investigator of very high rank. Probably the very qualities of mind which gave his character its value were in part an obstacle to abundant authorship. Many a memoir has seen the light because the author was ignorant of what had been done before; still many more have been thrust on the world because the authors were unable or unwilling to see the transparent fallacies of their own reasoning. No promptings of ambition were ever strong enough to lead Sharpey into either of these categories; or rather, let us say his ambition was too strong to permit him to publish much; his ideal of what a scientific memoir ought to be was so high that, after the first flush of the exuberant vigour of youth was over, he shrank from exposing himself to what, in his own judgment, whatever other men might think, would probably seem more or less of a failure.

There remains for us to recall to mind other features of Sharpey's character which, though dependent on his moral qualities, yet entered into all his intellectual work, and which were at the same time sources of his strength, and causes of such little weakness as he ever showed—his kindly disposition and his sympathetic nature. Without these his knowledge, large as it was, and his critical power, keen as it was, would not have had the effect they had. These moral qualities were conspicuous in him as a public man. His judgment made itself felt not only because of its intrinsic value, but because of the form in which it was given. Many a struggling inquirer has been warned off from dangers unseen to himself, or has been encouraged when desponding in his fight with that stubborn foe, Nature, by the friendly, often rather the paternal, counsels of him whose face we shall no more see. The same kindly nature and generous sympathy illumined his lectures also, and added to his strength as a teacher, for all his pupils looked up to him not only as master, but as friend.

Had Sharpey been more ambitious of fame in its commonly received acceptation, less unselfish, and perhaps we might add more combative in his disposition, he might have occupied a position in this country more conspicuous than that which he actually held, but this his friends cannot but think would, after all, have been a loss to them, and a very doubtful gain to him. His softness of heart, and his generous nature may even in some few instances have led him to befriend those who were scarcely worthy of his kindness. But the benefits of his noble devotion to science were freely bestowed around him on objects of high aspiration and lasting value; and the gentleness of disposition which some may have thought amounted to a fault, was counted by his friends as one of the great charms of his character. While they enjoyed the delights which intimate intercourse gave, of chatting familiarly with one who could converse on the most varied subjects with fulness of information and critical acumen, brightened with a lively sense of humour, and who could correct an error made in talking about the peerage as readily as a mistake about the structure of epithelium or the uses of the pancreatic juice, they nevertheless felt that the great worth of the man lay in the fact that in times of doubt and uncertainty they could come to him for the surest counsel,

Digitized by Google

and on occasions of difficulty and despair find words of cheering encouragement, and if needed, solid and material help. All these when they heard that William Sharpey was dead mourned chiefly for the loss of a friend whose grand unselfishness knew no speck of meanness.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on Tuesday last:—

Chadwick, James Morley, Heywood, near Manchester.
Clegg, Walter Thomas, Liverpool.
Day, William Aloysius, Hampstead.
Francis, Lloyd, Carmarthen.
Fraser, Donald Alexander, L.S.A., Weston-super-Mare.
Gripper, Arthur Douglas, L.R.C.P. Edin., Ware, Herts.
Harris, John Russell, L.R.C.P. Edin., Bayswater.
Hewitson, William Andrew, Newcastle-on-Tyne.
McDonagh, James Samual, L.S.A., Hampstead-road.
Matthews, Valentine, L.S.A., Torrington-square.
Paddle, James Isaac, L.R.C.P.L., Albert-street, N.W.
Puddicombe, William Noble, L.S.A., Edgware, Middlesex.
Reuner, Charles, M.D. Würzburg, Harley-street, W.
Richardson, J. H. Howard, Worcester.
Richardson, Charles Boards, Great Hadham, Herts.
Sayer, Mark Feetham, Finchley, Middlesex.
Spranger, Francis Jefferies, Cadogan-place, S.W.
Tooth, Howard Henry, Brighton.
Walters, Frederick Rufenacht, Croydon.
Wells, A. P. Lethbridge, Windsor.

The following gentlemen were admitted Members of the College on Wednesday last:—

Ashwell, Herbert George, Nottingham.
Bedford, W. G. Augustus, Sydenham.
Bovill, Henry Howard, L.R.C.P. Lond., James-street, S.W.
Bridges, Ashley Colston, L.S.A., Worcester.
Buller, Audley Cecil, Piccadilly.
Collier, William, L.R.C.P. Edin., Stapleford, near Cambridge.
Ewbank, Henry, Plymouth.
Farmer, Septimus, Nottingham.
Hill, Alexander, Lee, Kent.
Hoyle, William Evans, Newcastle-on-Tyne.
Jerome, John William, St. Helier's, Jersey.
Jones, Rees Rowland, Newcastle-on-Tyne.
Jones, William Clay, L.R.C.P. Edin., Llyswew, Brecenshire.
Langridge, Albert Henry, Dunstable.
Mead, Robert William, M.B. Edin., Whitby, Yorks.
Owen, Richard Jeffreys, Llandovery.
Pratt, Reginald, Billesdon, Leicester.
Sloggett, Arthur Thomas, L.R.C.P. Edin., Cambridge-gardens.
Tinker, Frederick Howard, Southport, Lancashire.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 15th:—

Alldridge, William Edward, Fonthill House, Birmingham.
Collier, William, Infirmary-road, Sheffield.
Counsellor, Charles Eye, Cradley Down, Sussex.
Meeson, Alfred, Mill-street, Liverpool.
Stacey, Herbert Gleeson, Park-square, Leeds.
Taylor, Thomas Percy, Bocking, Braintree, Essex.
Terry, Henry George, Bilbao House, Wells, Frome.

The following gentleman on the same day passed the Primary Professional Examination.:—

Bowman, Richard, St. Mary's Hospital.

ARMIRALTY, 19th April, 1880.—The undermentioned surgeons have been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of 23rd March, 1880:—Bernard Renshaw, John Adlan Robertson, M.B.

UNIVERSITY OF CAMBRIDGE.—Dr. Barclay, of Caius; Dr. Ransome, of Caius; Dr. F. S. R. F. De Chaumont, of Edinburgh; and Dr. W. H. Corfield, of Oxford, have been appointed examiners for the examination in State Medicine to be held next October. Also the degree of M.D. was conferred on John Abercrombie, Caius.

THE Government of the North-Western Provinces and Oudh has sanctioned a revised scale of rewards for the destruction of wild animals and venomous snakes.

AT the meeting of the Chatham Local Board of Health, on the 17th inst., a communication was read from the Local Government Board announcing their intention to send one of their inspectors to conduct an inquiry into the advisability of sanctioning a loan for the erection of an infectious diseases hospital for this district.

IT is proposed to form a Memorial Ward in connexion with the Sunderland Children's Hospital, as a mark of respect of the public character and services of the late mayor, Mr. T. S. Turnbull.

NATIONAL ORTHOPÆDIC HOSPITAL.—A course of lectures, by the surgeons of this hospital, on spinal curvature, club-foot, and genu valgum, has been announced to be delivered on May 5th, 12th, 19th, 26th, and June 2nd. These lectures commence at 5 P.M., and are open to members of the profession.

PRESENTATION.—A testimonial, subscribed for by the officials in connexion with the Sunderland Union, and consisting of a silver inkstand and pen and pencil-case, a ring set with pearls, &c., has been presented to Dr. C. N. Foote, on his retirement from the post of medical officer to the workhouse.

THE JOHN HUNTER MEDAL.—Dr. G. A. Woods, of Southport, to whom the collegial triennial prize of fifty guineas was awarded by the Council of the Royal College of Surgeons at its last meeting, has decided on taking the gold medal to that amount instead of the cash. This is the first occasion on which it has been so obtained.

VINCENT'S HOSPITAL, DUBLIN.—A special dispensary for the treatment of ophthalmic disease, and a ward for in-patients, have been established in this hospital, in consequence of the recent regulation of the Irish College of Surgeons requiring from candidates for the diploma in surgery a certificate of clinical instruction in ophthalmology. The dispensary and ward will be under the care of Mr. Denis Redmond, the recently appointed ophthalmic surgeon.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General John Alexander William Thompson, M.D., to be Surgeon-General, vice J. H. K. Innes, C.B., who is granted retired pay. Deputy Surgeon-General George Pain is granted retired pay, with the honorary rank of Surgeon-General. Surgeon William Alexander Duke to be Surgeon-Major. Surgeon-Major D. Murray, M.D., has been appointed to officiate as Principal Medical Officer British Forces, British Burmah Circle, in place of Deputy Surgeon-General W. A. Thomson.

THE HOSPITAL FOR WOMEN, SOHO SQUARE.—The report read at the annual meeting of the friends of this institution held last week, whilst exhibiting apparently a balance of receipts over expenditure during the past year, sets forth the need of further pecuniary aid to meet the increased outlay arising from the cost of eight additional beds now in use as compared with the accommodation in 1876. The medical officer's report showed that there were 45 patients in hospital at the commencement of 1879, and that 440 were admitted during the year, making a total of 485, of whom 229 were cured, 104 relieved, and 13 died; the remainder having either left at their own request or been discharged without benefit. Many important cases, it was stated, were, owing to the limited number of beds, necessarily delayed for weeks before they could be admitted. This is a fact which should have great significance with the benevolent.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET *before Half-past Ten on Thursday Morning, at the latest.*

ARMSTRONG, S., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Tiverton District of the Basford Union.

BARRETT, C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Sixth District of the Bath Union.

BROWNE, L., F.R.C.S.Ed., M.R.C.S.E., has been appointed Consulting Surgeon to the Newcastle Throat and Ear Hospital.

BUTLER, F. T., M.B., has been appointed Honorary Surgeon to St. Bartholomew's Hospital, Rochester, vice W. Buchanan, M.R.C.S.E., resigned.

CRESSWELL, T. H., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer and Public Vaccinator of the Third District of the Abingdon Union, vice J. H. Daly, resigned.

DUKE, A., M.D., M.R.C.S.E., L.S.A.L., has been appointed Consulting Surgeon to the Dover Hospital, on his resignation of the office of Honorary Surgeon to that institution.

FITZSIMON, C. C., M.B., has been appointed Assistant House-Surgeon to St. Bartholomew's Hospital, Rochester, vice W. T. Justeman, M.R.C.S.E., resigned.

FULLERTON, R., M.B., B.Ch., has been appointed Assistant Medical Officer to the City and County Lunatic Asylum, Stapleton.

HANHAM, F. W., L.R.C.P.Ed., L.F.P.S.G., has been appointed to the Fourth District of the Bath Union.

Digitized by Google

LEEPER, G. R., M.B., has been appointed Medical Officer to the Kilderney Dispensary District of the Irvinestown Union, vice B. J. Graham, M.R.C.S.E., resigned.

MACKAY, J. C., L.R.C.P.Ed., has been appointed Medical Officer to the Fourth District of the Halstead Union, vice W. Simpson, M.R.C.S.E., resigned.

MASON, W., L.R.C.P.Ed., has been appointed Medical Officer to the Second and Seventh Districts of the St. Austell Union, vice R. F. Stephens, M.R.C.S.E., resigned.

MILLS, R., M.R.C.S.E., has been appointed Medical Officer to the Benenden District of the Cranbrook Union, vice A. A. Blakiston, M.R.C.S.E., resigned.

PARSONS, F. J., L.R.C.P., M.R.C.S.E., has been appointed Medical Officer to the Morehard Bishop District of the Crediton Union, vice C. Snape, M.D.

PRINCE, H. F., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer for the Snettisham District of the Docking Union.

ROBERTS, N. E., M.B., has been appointed Assistant Resident Medical Officer to the Workhouse and Infirmary of the Township of Toxteth Park, Liverpool, vice C. R. Woods, M.D., resigned.

WARNER, F., M.D., M.R.C.P.L., has been appointed Lecturer in Botany at the London Hospital Medical School, vice J. G. Baker, F.R.S.

WILKINS, F. W., F.R.C.S.I., L.M.Q.C.P.I., has been appointed Demonstrator of Anatomy at the School of Surgery, Royal College of Surgeons, Ireland.

WATERS, D., Surgeon on the Staff of the Governor of Bombay, has been appointed Surgeon to the Oculdass Tejpal Hospital, Bombay.

WIGHTWICK, F. P., M.R.C.S.E., has been appointed Resident Clinical Assistant to the Brompton Consumption Hospital, vice E. Maudy, F.R.C.S., resigned.

WOOD, C., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Dover Hospital.

Births, Marriages, and Deaths.

BIRTHS.

BELFAMY.—On the 16th inst., at Wimpole-street, the wife of Edward Belfamy, F.R.C.S., of a son.

BROWN.—On the 19th inst., at The Willows, Tredegar, Monmouthshire, the wife of George Arthur Brown, of a son.

COCK.—On the 6th inst., at York Cottage, Peckham, the wife of W. Cock, Esq., Surgeon, of a son.

CLARK.—On the 6th inst., at Cavendish-square, W., the wife of Andrew Clark, F.R.C.S., of a daughter.

COTTON.—On the 10th inst., at Pentyffryn, Victoria-grove, Southsea, the wife of Dr. Cotton, Deputy Inspector-General, R.N., of a daughter.

DYTE.—On the 14th inst., at Upper Bedford-place, Russell-square, the wife of D. H. Dyte, L.R.C.P.L., of a daughter.

ELLIS.—On the 9th ult., at Sitapur, Oudh, the wife of John Ellis, M.D., Bengal Medical Service, of a son.

HARDING.—On the 20th inst., at North Lawn, Westgate-on-Sea, Kent, the wife of G. Clarence Harding, M.R.C.S.E., L.R.C.P.Ed., & L.M., of a daughter.

LITTLE.—On the 13th inst., at The Elms, Victoria-park, Manchester, the wife of David Little, M.D., of a daughter.

LUCEY.—On the 14th inst., at Southampton, Hants, the wife of William C. Lucey, M.D., of a son.

MARRIAGES.

BURT—HENDERSON.—On the 13th inst., at St. Giles's, Camberwell, Alfred Burt, M.R.C.S.E., L.S.A.L., of Bourton-on-the-Water, Gloucestershire, to Amelia Mary Henderson, second daughter of James Henderson, of Adon House, Dulwich.

HOLMES—BLOW.—On the 15th inst., at the Parish Church, Layer Breton, Thomas J. P. Holmes, M.B., Surgeon-Major, A.M.D., to Gertrude Charlotte Isabella, the eldest daughter of the Rev. William Blow, M.A., Rector of Layer Breton, Essex.

PHILIP—CRUICKSHANK.—On the 15th inst., at The Manse, Turriff, Aberdeenshire, by the Rev. D. Stewart, M.A., King Edward's, assisted by the Rev. J. Bathgate, M.A., Forgue, James Allan Philip, M.A., M.B., C.M., of Meniebank House, Midlothian, to Katherine Laura, youngest daughter of the Rev. John Cruickshank, D.D., Clergyman of the Parish.

WARNER—HOWARD.—On the 9th inst., at the Parish Church, Hampstead, by the Rev. Brooke Lambert, Vicar in charge of St. Jude's, Whitechapel, Francis Warner, M.D. Lond., M.R.C.P., of 15, Finsbury-square, to Louisa, eldest daughter of William Howard, Esq., of Lyndhurst-road, Hampstead. No cards.

DEATHS.

GOURLAY.—On the 20th inst., at his residence, Weston-super-Mare, Frederick Gourlay, Esq., M.D., in his 45th year.

HAMILTON.—On February 8th, on board the steamer *Garonne*, near Adelaide, Alexander M. S. Hamilton, M.D., M.R.C.S.E., of Ballymoney, late Medical Superintendent of Cheadle Union Infirmary, aged 29. New Brunswick papers will please copy.

HENRY.—On the 6th inst., at his residence, Claremont Cottage, St. Helier's, Jersey, James Henry, Esq., M.D., Staff-Surgeon, Bengal Navy, aged 61. R.I.P.

LOCKLEY.—On the 13th inst., at Bootham, York, Thomas Lockley, Esq., M.D., and J.P. for the West Riding of Yorkshire, aged 68.

MOORE.—On the 14th inst., Richard Read Moore, L.R.C.P., M.R.C.S.E., of Wolverhampton, second son of the late Thomas Moore, of The Wergs, aged 35.

STEWART.—On the 13th inst., at Arrochon, France, John Stewart, Esq., eldest and last surviving son of the late John Grant Stewart, M.D., C.B., Inspector-General of Naval Hospitals and Fleets.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

USE OF POISONOUS COLOURS.

THE Council of the Society of Arts, having had their attention directed to numerous cases of reputed poisoning by arsenical wall-papers and other articles in general household use, have appointed a Committee to inquire into the practicability of preventing the employment of arsenic in any processes by which it is alleged to remain in finished goods, and to obtain evidence as to the effects of total prohibition of the use of such processes, or the prohibition of the sale of articles produced thereby, would have upon various trades. To promote the object in view, this Committee has issued a circular to manufacturers of colours, dyers, and others using colours in manufacturing processes, asking for information on certain specific points. The following are the questions to which answers are asked for, such answers to be returned to the Secretary of the Society of Arts, John-street, Adelphi, London, W.C., on or before the 30th April:—1. In what colours, dyes, mordants, or other preparations used in trades or manufactures in this country is any preparation of arsenic employed? 2. For what other purposes and processes is arsenic employed? 3. Do you attach any special importance to the continued use of any arsenical colours or preparations, such as leave arsenic in the finished goods? and, if so, what preparations, and for what reasons? 4. Would it be any disadvantage to you if the use of such colours, dyes, pigments, or other arsenical preparations, both of home and foreign manufacture, were prohibited? and, if so, what disadvantage?

Styrax.—It is Guttmann's, not Kolitansky's, method. Last December Dr. Burney Yeo published a note on the subject in a contemporary.

NICTITATION.

To the Editor of THE LANCET.

SIR,—If your correspondent, under the above heading in your last week's issue, will try belladonna, I think he will find it of great benefit. In a case which came under my observation some time ago, I was induced to try it in this disorder from its well-known paralysing action upon the third nerve, and its administration was speedily followed by relief. These spasms and twitchings are associated by some with disorders of the digestive apparatus, but I have generally found them follow prolonged nervous exhaustion. There is no drug so speedily powerful in restoring strength and apparently nerve power. It is best administered in combination with hyoscyamus, and, in preference, I use the succus belladonnæ, fifteen minims, with succus hyoscyami, twenty minims, three times a day. If this should fail, large doses of cannabis indica might be of advantage.

I remain, Sir, yours &c.,

Liphook, Hants, April, 1880. T. FREDERICK PRIDEAUX, M.D.

Digitized by Google

ALDEHYD IN WHISKY.

AT a meeting of the Society of Medical Officers of Health, Dublin, held on the 15th inst., the President, Professor C. A. Cameron, read a paper of considerable length, "On the Quality of the Whisky on Sale in Ireland." As analyst for the largest proportion of Irish counties, large numbers of samples of whisky had been submitted to him for examination, chiefly by the Constabulary. Those collected at fairs, racecourses, wayside public-houses, &c., were generally of very bad quality. A certain proportion consisted of what was called "patent still" whisky, having but little in them save alcohol and a little flavouring matter—a kind of whisky which does not improve by being kept in wood, and which differs but little from the "silent spirit" imported from Germany. On the other hand, much of the whisky consisted of new whisky, containing fusel oil (amyl alcohol) and aldehyd. The latter is a substance formed by the oxidation of alcohol, and is intermediate between alcohol and acetic acid. Dr. Cameron regards it as a toxic ingredient of new whisky. It boils at 71·6°, and soon is changed, by absorption of oxygen, into acetic acid. It disappears when whisky is stored for a couple of years. Dr. Cameron states that in 1874 he suggested, when examined before a Committee of the House of Commons on Food Adulteration, that whisky should not be permitted out of bond until it was two years old, so as to allow of the oxidation of the fusel oil. He gave some instances of the poisonous qualities of new "poteen" (illicit whisky), and cited the case of a whole family poisoned by drinking for some months "poteen" containing 0·23 per cent. of amyl alcohol. Father and mother had become insane.

Dr. John Haddon.—We shall be glad to receive the "notes."

LISTER'S ANTISEPTIC DRESSINGS.

To the Editor of THE LANCET.

SIR,—In a paper which I read recently at the Royal Medico-Chirurgical Society, I brought forward statistics which seemed to me to point to the conclusion that the dressings of gauze and protection, upon which Mr. Lister and his disciples lay so much stress, are not only useless in giving greater security for the patient's recovery, but that they are positively hurtful by irritating the wound, and preventing speedy and complete union. In my experience it was an almost uniform result that wounds dressed after Lister's plan suppurated, and in many cases they sloughed; and though none of the patients died, many of the recoveries were anxious and protracted. Some of my critics said this was due to my imperfect method of using the dressings. My answer was that if the proper use of the dressings was above my intelligence, it was useless for general application, and that, whether I did or did not admit their criticism, I should go back to the old-fashioned dry lint. I have not done this exactly; but I have since employed Robinson's absorbent cotton-wool and gauze, as introduced to my notice by Mr. Sampson Gamgee, and I have had results as uniformly satisfactory as those from Mr Lister's gauze were disappointing.

I have now had fifteen ovariotomies, two abdominal explorations, and four excisions of the breast, in which I have used these absorbent dressings without any antiseptic preparation; and not only have all the cases recovered, but they have not given me five minutes' anxiety about their recovery, and the pus, if it could have been collected from the whole twenty-one cases throughout their course, would not have filled a tablespoon.

It is, therefore, to me conclusively proved that our improved results in abdominal surgery do not depend on Mr. Lister's dressings, at any rate; and now I intend to exclude the other details one by one, and place the results on record, whatever they may be.

I am, Sir, yours &c.,

Birmingham, April, 1880. LAWSON TAIT.

Unknown.—Our correspondent's letter, if published, would probably do more harm than good. A temperate statement of the grievance to the head of his service in India might lead to a modification of the rule in question; but it would be advisable to avoid making any personal remarks in it, such as occur in his letter forwarded to us.

Mr. Richard Paramore.—The use of Dr. Porter's name under the circumstances is very unjustifiable.

D. F.—We are not aware of any well-established cases of the trouble alluded to.

CONSTIPATION AS A DISEASE "PER SE."

To the Editor of THE LANCET.

SIR,—The discussion of this subject being most welcome to me and, I am certain, to many medical men practising in warm, relaxing climates, I beg, in the desire to see the matter gone into as fully as possible, and in support of Dr. R. Bell's views (THE LANCET, Feb. 14th), to state that the symptoms of chronic constipation may be found treated of in a separate chapter, under the heading of "Obstipatio Alvi," or "Stuhl-Verstopfung," in H. Lebert's "Handbuch der Practischen Medicin" (Tübingen: H. Laupp'sche, Buchhandlung).

Yours faithfully,

L. GOGOL, M.D., District Surgeon.

Murraysburg, Cape of Good Hope, March 16th, 1880.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the candidates at the pass examination for the diploma of Membership of the Royal College of Surgeons on the 16th inst., when 73 candidates presented themselves, who were required to answer at least four, including one of the first two, of the six questions:—

1. Describe the parts concerned in the operation for the relief of a strangulated hernia in the inguinal canal. Give the steps of the operation.
2. Describe the relations of the lower third of the brachial artery. Give the steps of the operation for tying it at the bend of the elbow. How is the collateral circulation carried on?
3. What are the local signs and constitutional symptoms of suppuration beneath resisting structures? Where is such suppuration likely to occur? Give the treatment.
4. Describe the structure of the different forms of nævus, and their appropriate treatment.
5. How would you diagnose the nature of a tumour in the anterior triangle of the neck?
6. Describe in detail the process of union of a simple fracture of bone.

The following were the questions on the Principles and Practice of Medicine submitted to those candidates on the following day (the 17th) who had not previously passed any examination on this subject:—

1. What are the chief causes of ascites? What are its symptoms and how would you recognise its presence? Point out the distinctions between it and ovarian and hydatid cysts and distended bladder. How would you treat it?
2. Give the morbid anatomy, symptoms, and treatment of acute pneumonia.
3. What are the properties, uses, and doses of the following drugs:—Tr. opii, pulv. opii, liq. morphiæ hydrochloratis, morphiæ hydrochloras, tr. cannabis indicæ, ext. cannabis indicæ, tr. colchici seminum, ext. colchici, liq. hydrargyri perchloridi, tr. ferri per chloridi, tr. ergotæ, tr. scillæ, oxymel scillæ, potassæ chloras, santoninum, and elaterium.

Ruination, (India.)—The promulgation of the G.O. regulating the administrative branch of the civil medical service has so completely altered matters that our correspondent's letter is now quite inapplicable. By the new arrangements the Indian Medical Service, instead of losing three surgeons-general and six deputy surgeons-general, has gained three deputy surgeons-general.

Incog. should transmit a copy of the Bill to the Bodies whose diplomas the practitioner in question holds.

EFFECTS OF AN OVERDOSE OF HYDRATE OF CHLORAL AND BROMIDE OF POTASSIUM.

To the Editor of THE LANCET.

SIR,—I do not know whether you may think the following a sufficiently notable case to refer to it in the columns of THE LANCET, or to permit this letter to appear, so as to elicit others' experience.

For some days before March 25th I had been taking a draught nightly, containing chloral hydrate, thirty-five grains; bromide of potassium, fifteen grains; spirit of chloroform, twenty minims; syrup of oranges, half a drachm; cinnamon water to an ounce and a half. On the night of March 25th, however, a mistake was made, and I was given chloral hydrate, three drachms and a half; bromide of potassium, a drachm and a half; spirit of chloroform, two drachms; syrup of oranges and cinnamon water as before. I took the whole, with the exception of about a drachm and a half, before discovering the mistake. I had just time to call for assistance before becoming unconscious. For eleven hours I was in a state of coma, and twenty hours passed before I regained consciousness. What my condition was during this time I can, of course, only gather from those around me. I am told my extremities became icy cold; that at first the action of the heart was accelerated, but after the first half hour its beating was scarcely to be felt. The throbbing of the head is described as being so violent as "almost to lift the top off." If the mouth was opened, so it remained; if closed, it remained so, as in a vice. Since recovery I have suffered from extreme weakness and nervous depression, with much pain in the back of the head of peculiar piercing character.

If recovery from such an exceptionally large dose is unique, the case may be of interest to your readers.

I am, Sir, yours faithfully,

April 7th, 1880. F. W. B., A MEDICAL STUDENT.

AN AWKWARD MISTAKE.

AT a charity dinner given on Tuesday evening, the chairman, a distinguished member of the Corporation of the City of London, asked for a fashionable effervescing mineral water. A bottle was accordingly produced, from which the worthy gentleman took about three-quarters of a tumblerful. It was not until the chairman and those who shared the bottle with him felt themselves called upon to retire somewhat abruptly, it was discovered that Hunyadi János had been given in mistake for Apollinaris!

SNAKE-BITE.

A CASE of snake-bite is reported in the *Australian Medical Journal* by Dr. Colin Henderson, of the Ararat Hospital. The patient was a girl, aged three years, who was bitten on the wrist by a tiger-snake. The wound was scarified and bathed, a ligature tied round the wrist, brandy given, and the child brought a distance of fifteen miles to the hospital. On admission she was lethargic, vomiting occasionally, respiration feeble, pulse slow and weak, pupils contracted, extremities cold. The wounded hand was purple and much swollen. The ligature was removed, a piece of lint soaked in strong liquor ammoniæ applied to the bite, constant friction with a liniment composed of equal parts of soap liniment and strong liquor ammoniæ applied over the heart and to the extremities, and ten minims of liquor ammoniæ with a drachm of brandy in a wineglassful of milk given every half-hour. Twelve hours after the receipt of the bite the patient was allowed to go to sleep, and she awoke three hours afterwards almost recovered.

Mr. R. W. Dawson had better consult a practitioner.

VACCINATION ON THE NOSE.

To the Editor of THE LANCET.

SIR,—The following case seems to me sufficiently interesting to merit publication :—

M. S——, aged thirty-eight years, came to the out-patients' room at this hospital, with a well-marked vaccine vesicle on the right side of the nose. Twenty-five days before, her male child, aged five months, had been vaccinated. The vesicle was rather a long time in coming to maturity, and the scab remained on later than usual. This child not unfrequently scratched his mother on the nose, and to this fact she attributes the inoculation. Five days ago she first noticed a pimple on the nose, and at the same time enlarged tender glands under the lower jaw. When she presented herself, there was a well-formed umbilicated vesicle on the right side of middle of nose, about half an inch by one-third of an inch ; much redness and induration of neighbouring tissues, and great swelling of eyelid ; enlarged tender glands beneath the angle of the lower jaw. She had three good marks on the left arm from vaccination when a child. She did not present herself again until the scab had fallen off. She had been so ill with increased inflammation about the face that she had been unable to leave home.

Your obedient servant,
JOHN C. UHTHOFF, M.D. Lond.,
House-Surgeon to the Sussex County Hospital.

Brighton, April 16th, 1880.

LEAD-POISONING.

DR. EMERSON REYNOLDS, at a recent meeting of the Royal Dublin Society, exhibited a frying-pan which had been sent to him for analysis, and on being tested gave proof of lead being present. The pan was made of the ordinary sheet iron ; but, instead of being coated with tin, had been covered with an alloy of tin and lead, the latter metal existing to a considerable amount. He narrated several cases which had come under his notice of persons being sufferers from severe choleraic symptoms due to having partaken of food cooked in pans of the sort described. Any food capable of yielding acid products is liable to take up the lead, or particles of the lead may become detached, or the oil or greasy materials used for cooking, which have the power of dissolving a quantity of lead oxide, may cause the lead to be present in the food in a more or less soluble state. There is little doubt but that the symptoms attributed to various disorders have occasionally been due to cases of irritant poisoning in consequence of the ingestion of lead from this or other sources.

Mr. Algernon Hamilton.—Each State has its own laws.

SCARLET FEVER IN A SEPTUAGENARIAN.

To the Editor of THE LANCET.

SIR,—Perhaps the following case may interest your readers, as I believe it is rare to find scarlet fever in a person of the undermentioned age :—

G. C——, aged seventy years, a male, has passed through a typical case of scarlet fever, with sore-throat and rash, and is at present peeling. So far he is doing well ; but it remains to be seen whether he will have any renal complication or not.

Your obedient servant,
JOHN BUCKLE, M.R.C.S.,
Resident Medical Officer, Farm-road Dispensary,

April, 1880. Brighton.

J. B.—The following gentlemen are members of the Court of Examiners : Mr. L. Holden (President) and Mr. W. S. Savory, of St. Bartholomew's Hospital ; Mr. F. Le Gros Clark, of St. Thomas's Hospital ; Mr. J Birkett, of Guy's Hospital ; Mr. J. Marshall, of University College Hospital ; Mr. T. Holmes, of St. George's Hospital ; Mr. J. C. Forster, of Guy's Hospital ; Dr. G. M. Humphry, of Cambridge ; Mr. J. Wood, of King's College Hospital ; and Mr. J. W. Hulke, of the Middlesex Hospital.

Mr. Harry T. Walsh.—We have no recollection of the case.

GREEN-STREET COURTHOUSE, DUBLIN.

A DEPUTATION from the General Purposes Committee of the Corporation of Dublin waited on the County Grand Jury on Monday last, in order to confer as to the necessity of improving the present condition of the courthouse. The building was constructed in 1795 ; but of late years its sanitary condition was found to be very imperfect, and the Corporation received last year a communication from the Lord Lieutenant enclosing a letter from the Lord Chief Justice, complaining of the want of sanitary arrangements, as well as of the limited accommodation. The question then arose as to whether certain alterations at an estimated cost of £6000 should be carried out, or an entirely new building erected at a cost of £20,000 ; but before determining the matter it was considered advisable to learn whether the Grand Jury would contribute towards the necessary outlay. The latter body have consented, if legally authorised, to bear part of the expenses, so that shortly we may expect that steps will be taken to remove what has been an opprobrium and disgrace to the authorities for many years.

J. B.—There are several varieties of the closet wished for. We advise a visit to the Parkes Museum any Tuesday, Thursday, or Saturday between 10 and 2, when a large number may be leisurely inspected.

MEDICAL DESTITUTION IN SARK.

IF we are to believe a statement which has got into print, the island of Sark is absolutely destitute of a resident medical practitioner. How the inhabitants, who number about 600, have hitherto managed in emergencies, and in stormy weather, it is difficult to understand, seeing that the nearest skilled assistance resides in Guernsey. It is satisfactory, however, to learn that the defect has at last become manifest to the ruling Court of Sark, who have resolved to contribute the sum of £40 annually towards making up any deficiency in the income which a surgeon might obtain by practising in the island.

PROLONGED LODGMENT OF A FOREIGN BODY IN THE EYE.

To the Editor of THE LANCET.

SIR,—In your issue for April 3rd you quote a case published by Dr. Chisolm, of Boston, in which a foreign body remained impacted in the iris for twenty-three years.

As an analogous case, I may quote that of a relation of my own, who in 1851 was struck with a chip of iron from an anvil. He was treated during several weeks for the resulting iritis ; but the *locus* of the foreign body does not seem to have been discovered, for he was not himself aware of its presence. He recovered with very fair sight of the injured eye, spent about sixteen years in India, and after his return home came casually under my notice for frequent attacks, apparently not inflammatory, but neuralgic, in the injured eyeball. On examination, I find the splinter of iron, rusted, but clearly visible, sticking in the anterior surface of the iris. As there was not the least symptom of sympathetic irritation, I advised watchfulness, and to abstain from meddling.

The case is interesting as being illustrative of the possibility of an eye remaining in an approximately healthy condition for twenty-eight years, notwithstanding the presence of a foreign body.

I am, Sir, yours truly,
April, 1880. ARCHIBALD H. JACOB, M.D. Dub., &c.

IDIOCY IN HOLLAND.

THE Annual Report of the Special School for Idiots at the Hague, which has been in existence twenty-five years, has been issued. The system of "boarding-out" appears to be adopted where possible, and with seemingly satisfactory results. Thus of 417 pupils who have been under the control and instruction of the institution since its foundation 148 were boarded out. Of the entire number, 43 have gone directly into service or adopted a regular trade, while 25, in a greatly ameliorated condition, have been discharged from the school. The number of persons suffering from varying degrees of idiocy in Holland is estimated at 3000, one-third of whom are deemed to be capable of education.

Mr. W. C. Hopgood.—We would advise our correspondent against the course he mentions.

Dr. Warren, (Boston, U.S.A.)—1. The meeting will be held in Cambridge.—2. Apply to the Secretary of the Association.

THE LATE DR. DONOVAN, OF SKIBBEREEN.

WE are asked to publish the following appeal :—Dr. Donovan lost his life by typhus just as he had successfully treated a great epidemic in his district. By his death his mother and five sisters are left unprovided for, and aid cannot be had from the Medical Benevolent Fund, which merely contributes to widows and orphans. Contributions for this most pressing and deserving case will be received by the Manager, Munster Bank, Skibbereen.

J. S. S.—We possess no information beyond that which our advertising columns supply.

A Teacher, (Leeds.)—There is no Collegiate law against a provincial Fellow being elected either on the Board or the Court of Examiners if he has time and inclination for its heavy duties. Dr. Humphry, of Cambridge, is already a member of the latter.

Mr. D. H. Cullimore.—We think the matter has been sufficiently discussed.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my note on "A Means of Diagnosis of Renal Calculus," appearing in your issue of to-day, I notice an omission which appears to me to take from the value of the suggestion. In giving the point for puncture with the needle, I am made to say simply "midway between the crest of the ilium and last rib"; whereas the words "and seven centimetres from the vertebral spines" were, or were intended to be, added in my MS. Yours faithfully,

ARTHUR E. BARKER.

Lumleian Lectures

ON

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.

Delivered before the Royal College of Physicians,

BY WM. ROBERTS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL MEDICINE TO THE OWENS COLLEGE.

LECTURE III.—PART I.

THE suggestion to administer to invalids artificially-digested food appears at first sight a somewhat startling proposal. So great an interference with the order of nature would seem to go beyond the legitimate province of art; but when we reflect how largely art already interferes in the preparation of our food, the taking of this further step will appear less surprising. The practice of cooking is in reality as complete a departure from the ways of untutored nature as artificial digestion would be. Among the almost countless species of animals, not one of them, except man alone, cooks his food, insomuch that man has, not inaptly, been defined as the cooking animal.

Effects of Cooking.—The process of cooking fulfils far more important ends than that of improving the savour of food—far more important even than the mechanical disintegration which generally attends the process. It produces certain chemical changes in several of the most important alimentary principles which render them incomparably more susceptible to the action of the digestive ferments than in the uncooked state. The discovery of the use of fire-heat in the preparation of his food must indeed have constituted one of the earliest and most important steps in the process by which man has emerged from the ranks of the dumb creation. The stores of proteid and farinaceous nutriment contained in the seeds of cereals and leguminous plants, and in the bulbs, tubers, roots, and succulent stems of certain vegetables, are, in the raw state, nearly altogether beyond his powers of digestion. By the discovery of the art of cooking these immeasurable stores were at one stroke laid open to him. It is moreover chiefly by the same art that he has been enabled to take his food at intervals, in separate meals, and has thereby been for ever relieved of the necessity which is imposed on all animals in the wild state of having to spend almost the entire of their waking hours either in seeking after their food, like the carnivora, or in consuming their food, like the vegetable feeders. This immunity secured to him the untold advantage of possessing the leisure requisite for the cultivation of his higher faculties.

The practice of cooking is not equally necessary in regard to all articles of food. There are important differences in this respect, and it is interesting to note how correctly the experience of mankind has guided them in this matter. The articles of food which we still use in the uncooked state are comparatively few, and it is not difficult in each case to indicate the reason of the exemption. Fruits, which we consume largely in the raw state, owe their dietetic value chiefly to the sugar which they contain; but sugar is not altered by cooking. Salads may be regarded more as a relish for other food, and as having a *quasi*-medicinal purpose, rather than as a substantial source of nutriment. Milk is consumed by us both cooked and uncooked, indifferently, and experiment justifies this indifference, for I found on trial that the digestion of milk by pancreatic extract was not appreciably hastened by previously boiling the milk.

Our practice in regard to the oyster is quite exceptional, and furnishes a striking example of the general correctness of the popular judgment on dietetic questions. The oyster is almost the only animal substance which we eat habitually, and by preference, in the raw or uncooked state, and it is interesting to know that there is a sound physiological reason at the bottom of this preference. The fawn-coloured mass which constitutes the dainty of the oyster is its liver, and this is little else than a heap of glycogen. Associated with the glycogen, but withheld from actual contact with it during life, is its appropriate digestive ferment—the hepatic diastase. The mere crushing of the dainty between the teeth brings these two bodies together, and the glycogen is at once digested without other help by its own diastase. The oyster in the uncooked state, or merely warmed, is, in fact, self-digestive. But the advantage of this provision is wholly lost by cooking, for the heat employed immediately destroys the associated ferment, and a cooked oyster has to be digested, like any other food, by the eater's own digestive powers.

With regard, however, to the staple articles of our food, the practice of cooking it beforehand is universal. In the case of farinaceous articles cooking is actually indispensable. When men under the stress of circumstances have been compelled to subsist on the uncooked grain of the cereals, they have soon fallen into a state of inanition and disease. By the process of cooking, starch is not merely liberated from its protecting envelopes, but it suffers a chemical change, by which it is transformed into the gelatinous condition, and this enormously facilitates the attack of the diastatic ferments. A change of equal importance seems to be induced in the proteid matter of the grain. I found that the gluten of wheat was incomparably more digestible, by both artificial gastric juice and by pancreatic extract, in the cooked than in the uncooked state. In regard to flesh meat the advantage of cooking consists chiefly in its effects on the connective tissue and the tendinous and aponeurotic structures associated with muscular fibre. These are not merely softened and disintegrated by cooking, but are chemically converted into the soluble and easily digested form of gelatine. I made some instructive observations on the effects of cooking on the contents of the egg. The change induced by cooking on egg albumen is very striking. For the purpose of testing this point I employed the solution of egg albumen before spoken of, made by mixing white of egg with nine times its volume of water. This solution when boiled in the water-bath does not coagulate nor sensibly change its appearance, but its behaviour with the digestive ferments is completely altered. In the raw state this solution is attacked very slowly by pepsin and acid, and pancreatic extract has almost no effect on it; but after being cooked in the water-bath, the albumen is rapidly and entirely digested by artificial gastric juice, and a moiety of it is rapidly digested by pancreatic extract.

My object in making these remarks is to show that the changes impressed on food by cooking form an integral part of the work of digestion—a part which we of the human race get done for us by the agency of fire-heat—but a part which the lower animals are compelled to perform by the labour of their own digestive organs. It must also be borne in mind that the digestive process carried on in the alimentary canal is, strictly speaking, executed on a doubling of the exterior surface, and not in the true interior of the body. If we take all these considerations into account, it would appear, I think, not unnatural that we should try to help our invalids by administering their food in an already digested, or partially digested, condition. We should thereby only be adding one more to the numberless artificial contrivances with which our civilised life is surrounded.

PREPARATION OF ARTIFICIALLY-DIGESTED FOOD.

Dr. Pavy[1] was, I believe, the first to carry into actual practice the idea of preparing an artificially-digested food. At his suggestion, Messrs. Darby and Gosden introduced a preparation which consisted of meat reduced to a fluid state by artificial digestion. The formula for this preparation has not, so far as I know, been made public. It is still in the market, and is sent out and advertised by Savory and Moore under the title of "Darby's Peptonised Fluid Meat." A specimen of this preparation is on the table before me. It has the appearance of a light brown very thick treacle. It has a strong salt taste and an agreeable meaty flavour, without any bitterness. It is mostly soluble in water. The solution does not precipitate on boiling, nor with nitric acid, and it gives a strong reaction of peptone, with Fehling's solution, and with tannin.

I have also before me a specimen of artificially-digested meat prepared by Mr. Benger. It is a greyish-looking extract, with a pleasant meaty flavour, and is quite devoid of bitterness. It dissolves mostly in water, and the solution

[1] A Treatise on Food and Dietetics. 2nd ed., p. 559.

Digitized by Google

gives the usual reactions of peptone in great intensity. Mr. Benger informs me that it is made by operating at a temperature of about 140° F., on finely triturated raw beef with pancreatic extract and a little carbonate of soda. The solution thus obtained is neutralised with hydrochloric acid, and then evaporated at 212° F. to the consistency of a solid extract. Both of these preparations appear to me to be much superior in value to any of the meat extracts hitherto introduced.

But, however useful preparations of this class may prove to be, in a limited range of circumstances, it is pretty evident that if artificially-digested food is to be employed on the large scale, and among all classes, means must be found to bring the preparation of it within the range of culinary operations and the apparatus of the kitchen and sick-room.

The difficulty hitherto encountered in the production of an artificially-digested or peptonised[2] food, suitable for invalids, is mainly owing to the use of the gastric method in its preparation. If you subject any native article of food—say milk, bread, egg, or meat—to artificial digestion, with pepsin and hydrochloric acid, you destroy more or less completely the grateful odour and taste, and the inviting appearance, which made it desirable as food, and convert it into an unsavoury mess, from which the human palate turns away with disgust. The unsavouriness of artificially-digested food is, however, not due to any ill taste or smell inherent in the products of digestion—which, when purified, are both odourless and free from any unpleasant flavour—but to a number of bye-products of various kinds, which accumulate as digestion proceeds. One of these bye-products is a substance with a pure bitter flavour, which seems to be a constant accompaniment of gastric digestion. It is also developed, in some cases, in the later stages of pancreatic digestion. I have not observed this bitter substance, except in the digestion of proteids. It is evidently a normal educt of the process, and its presence probably accounts, in most cases, for the bitter flavour of the eructations, of which dyspeptics complain, and which is generally attributed to the regurgitation of bile. It would be interesting to know more about this substance.

My own efforts to produce a palatable peptonised food have been chiefly directed to the pancreatic method. The pancreas excels the stomach as a digestive organ, in that it has power to digest the two great alimentary principles, starch and proteids; and an extract of the gland is possessed of similar endowments. This double power is a manifest advantage in dealing with vegetable aliments, which contain both starch and proteids.

Any extract of pancreas may be used for the preparation of artificially-digested food, but the most suitable are those prepared with dilute spirit or chloroform-water. The extract sent out by Mr. Benger, under the name of "Liquor Pancreaticus," is an almost faultless pharmaceutical preparation. It is made by extracting perfectly fresh and finely-chopped pancreas, with four times its weight of dilute spirit. By some ingenious devices, Mr. Benger has succeeded in overcoming the mechanical difficulties of the manufacture, and has produced an extract which possesses the diastatic and proteolytic properties of the pancreas in a highly-concentrated degree. It is a nearly colourless solution, with very little taste or smell beyond that of the spirit used to preserve it. It is of this preparation that I must be understood to speak in what I have now to say on the production of artificially-digested food by pancreatic extracts.

My attention was first turned to the artificial digestion of milk, and I soon found that it was possible, by means of pancreatic extract, to digest this important article of food with comparatively little disturbance of its taste and appearance. Milk contains all the elements of a perfect food, adjusted in their due proportion for the nutrition of the body. Two out of its three organic constituents—namely, the sugar and the fat—exist already in the most favourable condition for absorption, and require little, if any, further assistance from the digestive ferments. It is therefore obvious that if we could change the casein of milk into peptone without materially altering the flavour and appearance of the milk, such a result would go far towards solving the problem of supplying an artificially-digested food for the use of the sick.

Pancreatic Digestion of Milk.—When milk is subjected to the action of pancreatic extract, at a temperature of 100° F. (38° C.), in an open glass vessel, a series of changes take place in it which are highly interesting to watch. The first thing that arrests the observer's notice is that the tough wrinkled skin which quickly forms on the surface of warm milk when exposed to the air is either not produced at all, or is only produced in a very imperfect degree. In its stead there forms a slight brittle and perfectly smooth pellicle of quite a different appearance. The next thing noticed is that the milk becomes more or less softly curdled. By and by the curds begin to redissolve, and the milk gradually reassumes its originally diffluent condition. A portion of the curd is, however, very resistent, and remains undissolved for many hours. If the milk be diluted beforehand with one-third or one-fourth of its bulk of water, this curdling phase is altogether omitted, or is only observed as a slight and transient thickening. Next follows a very curious change of aspect. The milk loses its glossy white appearance, and gradually assumes a dull yellowish-grey shade which is characteristic, and the degree of which enables the practised eye to judge with considerable precision how far the peptonising process has advanced. This change of aspect is, however, by no means conspicuous, and would scarcely be remarked in a cursory observation, except by comparison with unaltered milk. While these changes are proceeding, the milk gradually loses its proper flavour, and at length develops a pure bitter taste, which is to many palates not disagreeable. No really unpleasant flavour is produced, unless the process is allowed to go on to incipient decomposition.

The progressive transformation of the casein into peptone, of which these outward signs are the indications and accompaniments, may be followed by testing the milk from time to time with acetic acid. At first the addition of the acid causes an abundant precipitation of curdy matter, but this reaction progressively diminishes in intensity until at length it ceases altogether. When this point is reached the transformation may be regarded as complete. All the casein has been changed into peptone—even nitric acid no longer causes a precipitate. The time occupied in the transformation (supposing the temperature and the activity of the preparation to be constant) depends on the quantity of pancreatic extract added, and may be made to vary from a few minutes to several hours. In the ordinary operation of preparing peptonised milk for invalids, two or three teaspoonfuls of the liquor pancreaticus are added to one pint of milk, diluted with a fourth of its bulk of water. With these proportions the process is usually completed in from two and a half to three hours.

[2] I may be permitted to use the word "peptonised" as a convenient abbreviation for the phrase "artificially digested."

Clinical Lectures
ON
LOCOMOTOR ATAXIA.

Delivered at the National Hospital for the Paralysed and Epileptic,

BY THOMAS BUZZARD, M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL.

LECTURE III.

AT the last lecture I exhibited three patients affected with tabes dorsalis. B—— was a typical case of the disease, with ataxic gait and inco-ordinate movements of the hands, lightning pains of excruciating character, and diplopia, amongst other symptoms. A—— had no ataxia of gait, but all the other characteristics of tabes were well marked. V—— was a thoroughly representative case, with no symptom wanting to complete the picture. All three, you will remember, showed entire absence of patellar tendon-reflex, the quadriceps extensor muscle retaining at the same time its normal capacity for being excited to contraction by a blow or by induced electrical currents.

Now in each of these cases, there was that condition of pupil to which attention was first called by Argyll Robertson.[1] The pupils do not contract to light, but they do

[1] Edin. Medical Journal, December, 1869: See also an interesting article on the eye-symptoms in locomotor ataxia, by Dr. Grainger Stewart: Brain, July, 1879.

Digitized by Google

contract during accommodation. I purposely refer to this peculiar condition of the pupil just now, because it seems to me that it constitutes a further instance of that removal of reflex in tabes of which so remarkable an example is offered by the absence of response to a blow upon the patellar tendon. The symptom is of great importance, for it is extremely frequent. Some highly interesting experience has been published by Vincent on this point.[2] Out of fifty-one tabetic patients which he had the opportunity of observing in Charcot's clinique there were only four whose pupils reacted normally. In seven there was complete immobility of the pupils (usually combined with amaurosis), and in forty the pupils did not react, or reacted imperfectly, to light, but contracted during accommodation.

It occurred to me that the ophthalmoscope would offer a convenient mode of testing this symptom, the examination thus being able to be made at the same time that the state of the fundus oculi is observed. The following is the mode of examination which I have devised, and which answers perfectly. The patient should be directed to look over your shoulder at some object in the distance. With the ophthalmoscopic mirror you then cast a strong light upon his eye, whilst at the same time you watch for any variation in the size of the pupil through a convex lens of about +12 placed behind it. Supposing that the pupil does not contract to light, the patient may next be told to look alternately at the distant object and at one almost in a line with it, but within ten inches (or still nearer, if he be myopic) of his eye. Uniform illumination of the surface of the eye should be maintained during the continuance of the examination, and the diameter of the pupil watched as the patient's gaze is shifted from one object to the other. It is necessary to be careful that no fallacy creeps in from the patient regarding your face (and thereby accommodating), when he should be looking at a distant object.

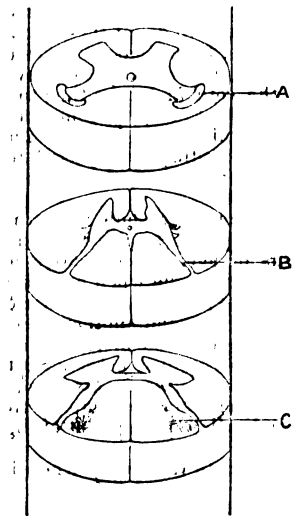
It appears to me (and I am alone responsible for the suggestion) that a very interesting generalisation can be derived from this symptom. It may be put as follows. As I have said before, in a large proportion of cases of tabes the natural movement of the iris consequent upon light falling upon the eye does not occur, or occurs only slightly and imperfectly. The iris does move, however (the pupil contracts), when the patient looks at an object placed near to his face. Now, to quote Donders, "the movements of the iris are of two kinds, reflex and voluntary. Reflex action is exhibited as constriction of the pupil in consequence of the stimulus of incident light upon the retina." It is this reflex movement which is so frequently abolished or impaired in tabes. The movement (contraction of the pupil) which is associated with accommodation for near objects, and which, as Donders shows, is to be considered voluntary, remains, in the large majority of cases, unimpaired. We cannot help seeing in this a remarkable analogy with what happens in the leg. The tabetic patient can kick his foot upwards—i. e., voluntarily contract his quadriceps extensor muscle—perfectly well. The contraction, however, which in a state of health follows, by reflex action, the stimulus of a blow upon the patellar tendon, does not occur, or occurs only to a limited extent. Time will not permit me to go further into this interesting point. I would only remark that the fact described lends additional support, so far as it goes, to Pierret's view, that tabes essentially attacks the *sensory* side of the cerebro-spinal nervous system. Reflex movements, as we know, are excited by impulses which travel along afferent (sensory) nerves.

In the three patients referred to an important symptom has occurred in addition to those which have been already described. B—— has suffered occasionally from "darts of pain from one side of his head to the other." A—— has anæsthesia of the left half of his face and the interior of his left cheek. "In eating he is apt," he tells us, "to bite the cheek." He can feel but little on the left half of the tongue, and his taste on that side is not so perfect as on the right. He does not feel a touch (I learn from Mr. Brooster's notes) on the left half of the palate, and scarcely on the left half of the pharynx. He also suffers from pains in the back of his head." V——, when he came to us, was affected with facial paralysis of the right side, which had immediately followed severe electric-shock-like pains of three weeks' duration. I shall have to show you a fourth case, in which one-half of the face and tongue is anæsthetic; a fifth case, in which the lightning pains in the head have been so severe as to give rise to the suspicion of intracranial tumour, and a sixth case, which began with sharp shooting pains in the head.

In these three patients we have pains or anæsthesia occurring in some part of the head. How are we to explain this in a disease which affects in so pronounced a fashion the posterior columns of the cord and posterior roots of spinal nerves? As regards the pains which A—— experiences at the back of his head, they occur in the district principally innervated on each side by the great occipital nerve, the internal branch, you will remember, of the posterior division of the second cervical nerve. We have, therefore, to do with a spinal nerve, after all, although its distribution is to the head. It is evident that such a mode of irritation of its posterior root as causes, when the posterior roots of the nerves supplying the trunk and extremities are in question, the characteristic "lightning pains" in them, is sufficient to explain the occurrence of similar pains at the back of the head.

In the two other cases the pains occupy the district supplied by the fifth nerve. According to Quain the sensory portion of the fifth nerve arises from a collection of grey substance beneath the outer part of the floor of the fourth ventricle in its middle third. In front of the nucleus a bundle of descending fibres mingled with much grey matter passes down to the lower part of the medulla oblongata. Huguenin describes this descending root as forming at this point a crescent, which encloses the gelatinous substance of the posterior horn. Hence it can be traced as low, it is thought, as the level of the third or fourth cervical vertebra.

In the accompanying diagram the crescent-like cup of the posterior horn (A) represents the descending or spinal root of



the trigeminus about where the medulla oblongata ceases and the cord begins. B indicates the posterior root zone of the second cervical nerve (the sensory origin of the great occipital nerve). The lowest section in the diagram is supposed to be at about the level of the fifth cervical nerve, and C shows sclerosis of the posterior root zone, the seat of the essential change in tabes. It is evident, then, that an extension upwards to B and A of the changes connected with the posterior root zones of the cord (C) must involve in succession the sensory origin of the great occipital nerve and the descending root of the trigeminal, and in this way we have the nerves which supply between them almost all the integument of the head and face in continuous relation with that particular system of fibres, sclerosis of which gives rise to the pains of tabes.[3] Now, it occurred to Pierret to search for changes in the descending root of the fifth in a case of tabes. In a certain case he found that there did exist around this inferior nucleus of the trigeminal nerve

[2] 'Des phénomènes oculo-pupillaires dans l'ataxie locomotrice et la paralysie générale des aliénés.' Par Ch. Vincent: Paris, 1877.

[3] For the sake of simplicity the great occipital nerve is alone considered. The remarks apply equally, of course, to the small occipital and great auricular branches of the second and third cervical nerves.

Digitized by Google

a well-defined sclerosis, the form and connexions of which recalled exactly what is found in the cord of ataxic patients. With this fact before us, and bearing in mind the relations which I have described, we shall not be surprised to find that symptoms pointing to lesion of the sensory portion of the fifth nerve and the great occipital are really very common in tabes. It is remarkable that this is a point which is frequently to a great extent overlooked, the oculo-motor symptoms and those belonging to the extremities having to a large extent monopolised attention. From a diagnostic point of view its recognition is important. Unless we bear in mind this contingency, a patient's description of intense pain in the head, so severe as to dwarf other symptoms by contrast, is liable to put us off the scent of tabes dorsalis. May not certain cases of obstinate cranial neuralgia prove to depend upon sclerosis limited to a certain district of the medulla oblongata? It is worth considering whether there are any points to guide us in reference to this possibility.

In an ordinary case of trigeminal neuralgia it is most common to find the pains limited to the district of one or more of the three divisions of the nerve, and it is not often that exploration fails to discover one or more tender spots in situations where experience leads us to expect them to be found. But in the pains (otherwise neuralgic in character) which occur in the region of the fifth nerve in tabes, this accurate mapping out of the district of one or other division of the nerve is not, according to my experience, observed. Moreover, the pains are much more liable than in the case of ordinary tic to affect both sides of the head, either coincidently or in turn. And this is what might be expected; the changes in the posterior columns being disposed to attack more or less symmetrically, though usually not with equal violence, the two sides. The same remarks apply to the occipital nerves. In occipital neuralgia, ordinarily so termed, on the other hand, the district of one or other nerve, not of both, is usually the seat of pain. Flying, so called "neuralgic" pains in the head, then, *when they attack both sides and do not map out the district of one or other division of the fifth nerve*, should lead to attentive examination for symptoms of tabes. No doubt these may be wanting, as it is quite conceivable, from what we know of the pathology of posterior sclerosis, that the disease may commence in the upper part of the cord and take time to descend; or even, there is reason to think, may, in some cases, remain limited to the locality in which it originated. But at a later period symptoms may be ordinarily expected to show themselves which will tend to refer the pains in the head to a tabetic origin.

The patient whom I now show to you presents a striking example of the cephalic symptoms of tabes. J. D—— is forty-nine years of age, by occupation a sweep. He had small-pox badly, and ague when he was a lad, and he has also suffered from syphilis. A daughter of his is imbecile, one of his sons has fits, and another, who is now blind, had fits in infancy. There is no history of a fall or mechanical injury. The patient applied here in September last on account of *excruciating pains in his head*, "as though," he said, "it was being scranched up." He was blind, there being only qualitative perception of light with the left eye.

Now, intense pain in the head, when it is coupled with amaurosis, is very suggestive of the presence of an intracranial tumour, and the idea that the patient was suffering from some encephalic growth crossed my mind at once, as he began to tell his story. When we came to examine him with the ophthalmoscope, we found that both optic discs were atrophied. Now this was, in the circumstances, to be expected, and the information which the fact afforded, although important, was not conclusive. If instead of atrophy of the discs we had found optic neuritis, this condition, when taken in connexion with the intense severity of the pain in the head, would have gone far towards enabling us to pronounce a somewhat confident diagnosis of intracranial tumour. But the condition was one of atrophy, and atrophy, as you are aware, may be (to speak only of two causes) either a consequence of optic neuritis or due to posterior sclerosis. Now, in most cases in which the atrophy is recent one has not much difficulty in saying to which category a particular example is to be referred. When atrophy succeeds optic neuritis, there is usually to be found for some time afterwards more or less trace of effusion about the disc, the edge of which frequently wears a blurred look. The artery is often diminished in calibre, and the veins may retain more or less of the tortuosity by which they were characterised when the disc was swollen. In sclerosal atrophy, on the other hand, these signs are wanting, and the vessels, undiminished in size, appear as if applied against an opaque white or bluish-green disc, which presents a clear and sharply-cut outline. But these distinctions are not always so pronounced, and in this particular instance one would have felt disinclined to say positively whether the observed atrophy had resulted from optic neuritis or not.[4] It is true that there were no signs of antecedent swelling of the disc or effusion, and no tortuosity of the vessels, such as one commonly sees after optic neuritis. But it is surprising how completely the swelling of a disc may after a time disappear, and what little evidence of the nature of past changes is sometimes left. The ophthalmoscopic signs, therefore, although they pointed only to a wasting of nerve-fibres, with overgrowth of connective tissue, were not, properly speaking, conclusive, especially when the condition was taken along with the clinical history of terribly severe pain in the head. I may mention here that I lately examined after death a man who had incomplete atrophy of the optic disc in one eye, and some amblyopia in the other. His symptoms were purely cerebral, and he died of brain softening. Yet my colleagues, Dr. Hughlings Jackson and Dr. Gowers, who were kind enough to examine the eye independently during life, were of opinion that the atrophy was not secondary to neuritis, and Mr. Brudenell Carter, who also obliged me by examining him, thought that it was of the kind seen in locomotor ataxia—a sclerosal atrophy, in fact. I was, for my own part, doubtful, but more disposed to think it secondary to neuritis, for one or two of the veins at some distance from the disc were somewhat more tortuous than appeared natural. However, after death, I found a small tumour pressing upon the left optic tract, and flattening it. Such pressure might cause an atrophy, which would be indistinguishable from that of tabes. Whether or not there had been at any time antecedent neuritis in connexion with the presence of the tumour must remain, I think, very doubtful. At any rate, there was cause enough for the atrophy in the pressure of the growth. I mention the case as an illustration of the doubt which may sometimes exist upon this point, and as a reason why, in a man who came to us with optic atrophy, and intense pain in the head, I did not feel inclined to decide at once whether his case was one of intracranial tumour or not. Our next step was to test his patellar tendon-reflex. It was absent in both legs. Here was evidence, therefore, at once of the existence of a spinal lesion. This reflex is not lost as a result of cerebral lesions, so that, whatever else there might be (and this, of course, did not preclude the existence of an intracranial growth), there was lesion of the spinal cord or spinal nerves. The clue thus given was followed up, and the following results elicited. Two years and a half previously his sight began to fail, the right eye first. At times he saw double. For some years he had been subject to pains in his thighs, on and off "very quick indeed"; "like an electric shock," he said, "sometimes so sharp that he would jump up, or be obliged to get up and straighten his limbs." The pains in the head, upon which I have insisted, did not begin till about two years previous to his coming under observation, when the pains in the limbs had already existed for a long while. He worked, it seems, up to Christmas, 1878, but then found that he could not see the numbers on the doors of the houses. He was not aware that he staggered until October, 1878, when, whilst sweeping a chimney in a lady's house, he was ordered out "on account of being drunk," being at the time, he pleads, perfectly sober. Latterly, the pains have affected the arms as well as the legs and head. The patient's own description of the pains, as taken down by Mr. Broster, is very characteristic. "It is like," he says, "a violent shock of rheumatics coming lightning speed up and down your limbs, flying up and down." There is no loss of cutaneous sensibility anywhere, but when he is in bed he does not know where his feet are. The muscular power of his limbs is not very perceptibly impaired, but he says that his right leg seems to be getting weak. His pupils are very small indeed. They do not contract to light, but they contract during accommodation.

There can be no doubt that the patient is suffering from tabes dorsalis, and as little, I think, that the optic atrophy is sclerosal, and the pains in the head due to lesion of the descending root of the fifth, and probably also of the great

[4] Gowers, in his able work on Medical Ophthalmoscopy, remarks of "primary" and "secondary" atrophy, "it is doubtful whether the two forms can be distinguished by the ultimate aspect of the disc."

Digitized by Google

occipital nerves. The pains he tells us affect both sides of the head, and the forehead.

Whilst upon this subject of optic atrophy, I will show you another man who has been kindly sent to me by Mr. Macnamara. He is a labourer, forty-four years of age, who besides suffering from aortic regurgitation, is affected with incomplete atrophy of both optic discs, but especially of the left. The disc presents a lustre like that of a tendon. When asked if he had difficulty in walking, he said he "could walk as well as ever he did in his life," and illustrated his assertion by a very fair performance. You see, indeed, that there is nothing in his gait which would be likely to attract your attention. His pupils are small. There is a very slight reaction in the right one, and the left does not contract at all to light; but they both act well enough during accommodation. He tells us, and I have inquired most carefully on this point, that he has never had any pain whatever, neither had he seen double; but when we tested his patellar tendon-reflex, we found that there was none in either leg, and when we inquired more particularly about staggering, he allowed that his brother when walking with him had more than once said, "Why, anyone would think you were drunk."

With the exception, then, of this reported stagger, only occasionally observed, the patient presents no sign of tabes to help us in our diagnosis of the cause of the optic atrophy, except the absence of patellar tendon-reflex, and the existence of the "Argyll Robertson symptom" (to use Dr. Grainger Stewart's designation). Can we doubt that they are amply sufficient?

But where even one of these two symptoms is absent I am disposed to think that in certain cases we may make our diagnosis with a good deal of confidence. I will give you an instance. A gentleman, aged thirty, was lately brought to me by Dr. Roose, of Brighton, on account of increasing blindness, supposed to be due to lesion of the central nervous system. The patient had enjoyed excellent health except for an attack of syphilis five years previously. Last May he found that vision with the right eye was failing, and this difficulty has gradually increased, so that there is now only qualitative perception of light with it. It was some time after the right had begun to fail that he found the left eye going also in the same way. On examination with the ophthalmoscope I found what appeared to me to be the signs characteristic of grey degeneration (sclerosal atrophy) of each optic nerve, most advanced in the right. The discs presented no atrophic excavation. They had a tendinous lustre, the veins were rather large in proportion to the arteries, and there was a slight tortuosity in one of them. Patient's perception of colour was imperfect. Scarlet was called "brownish-yellow," green "slaty-brown," a vivid magenta "pale blue." Blue and yellow were described correctly. Careful inquiry showed that he had never had any pain in the head, vomiting, or any other cerebral symptom, such as might have been expected were the atrophy the result of optic neuritis. But, on the other hand, there had been no flying pains in his limbs nor diplopia. Nor was there any ataxia of gait or tottering with the eyes shut. The pupils acted readily to light. There was no anæsthesia, and no trouble with the genito-urinary organs. There was nothing indeed to be noted but the gradually increasing atrophy of both optic nerves. With one exception. I found the patellar tendon-reflex absent in the right leg, and present to only a slight degree in the left. The quadriceps extensor muscle responded readily to blows upon it and to induced currents.[5]

If I have succeeded in conveying an idea of the importance of this test, as exemplified in many forms of the disease we are considering, you will, I think, be disposed to see in this case, as I do, one of tabes dorsalis, which as yet presents itself in a very restricted form.[6]

[5] Since the above was written the tendon reflex has disappeared also from the left leg.

[6] Fourteen years ago Dr. Hughlings Jackson pointed out, in the Medical Times and Gazette, September, 1866, that there was at least a clinical gradation in the symptoms from what was called "uncomplicated amaurosis" to locomotor ataxia. He founded this idea upon the occurrence of characteristic shooting-pains in many cases of amaurosis, in which the ophthalmoscopic changes in the discs were of the character of those met with in tabes. He believed that amaurosis was sometimes the first symptom of this disease. For some time past this view has been accepted, and cases of optic atrophy, with lightning pains and without other symptoms, have been classed with locomotor ataxia. It is only since quite a recent date that Westphal's observations in reference to absence of patellar tendon-reflex have brought us the most important confirmation of this view in the occurrence of the symptom, as in the last case, where none of the other recognised signs of locomotor ataxia have presented themselves.

LIVER ABSCESS AND ANTISEPTIC PARACENTESIS.

BY SIR J. FAYRER, M.D., F.R.S.

(Continued from p. 635.)

I AM indebted to Surg.-Major Don, A.M.D., for the following information respecting the relative frequency of hepatitis and liver abscess in European soldiers in foreign stations:—

Year.	Strength.		Admitted.	Died.	Invalided.
Bengal.					
1870	34,090	Hepatitis	1920	152	249
1871	35,452	Hepatitis	1919	5	241
1872	36,839	Hepatitis	1814	3	210
		Abscess	89	55	43
		Ab. with dysent.	45	43	—
Madras.					
1870	9,936	Hepatitis	635	41	131
1871	10,684	Hepatitis	713	41	58
1872	10,892	Hepatitis	586	5	70
		Abscess	43	35	—
Bombay.					
1870	10,557	Hepatitis	424	11	49
1871	10,838	Hepatitis	464	18	30
1872	10,898	Hepatitis	350	12	41
		Abscess	12	8	—
China.					
1870	546	Hepatitis	15	0	1
1871	516	Hepatitis	8	0	0
1872	789	Hepatitis	15	1	0
		Abscess	1	1	—
Japan.					
1870	624	Hepatitis	15	1	1
1871	395	Hepatitis	6	1	0
1872	—	—	(No returns for this year)

1872	2484	Hepatitis	23	1	3
West Indies.					
1870	1432	Hepatitis	2	0	0
1871	966	Hepatitis	12	0	0
1872	1112	Hepatitis	2	—	2
		Abscess	1	0	0
Bermuda.					
1870	1908	Hepatitis	8	0	1
1871	1733	Hepatitis	6	0	2
1872	1770	Hepatitis	5	0	0
Canada.					
1870	4519	Hepatitis	10	0	0
1871	2383	Hepatitis	12	1	1
1872	1602	Hepatitis	3	0	9
Gibraltar.					
1870	4397	Hepatitis	17	0	4
1871	4428	Hepatitis	16	0	6
1872	4066	Hepatitis	9	0	4
Malta.					
1870	4799	Hepatitis	26	5	6
1871	4977	Hepatitis	26	2	7
1872	4855	Hepatitis	27	0	4
		Abscess	2	1	0

From these returns it will be seen that the disease is more prevalent in India than in the West Indies.

Digitized by Google

It is thought by some that liver abscess is due to absorption of septic matter from dysenteric ulceration in the bowel; others have thought that liver abscess is the cause, and not the result, of dysentery. I am inclined to regard them as independent, though often co-existent, and due to the same climatic causes; and I believe that it occasionally does *result* secondarily by absorption from the ulcerated bowel, and is then of the nature of pyæmic suppuration, in which case it is apt to be multiple, and more serious in character than the ordinary form of abscess.

The early symptoms preceding suppuration in the liver are those of congestion, swelling, pain, high temperature, fever preceded by chills or well-marked rigors, and sweats. There is cough, pain in the right shoulder and hypochondrium, inability to lie on the left side, owing to the weight of the swollen and dependent liver; nausea or vomiting, from pressure on the stomach, or irritation of the vagus; a yellow tinge of the skin and eyes; sometimes a high-coloured state of the urine and lithic deposits. These symptoms, together with the bulging of the side, between or below the ribs, leave little doubt of what has occurred. But there are cases in which the symptoms are not well pronounced, and yet an abscess may form and escape detection until bulging and fluctuation, or sudden evacuation of its contents through the bowels, the lung or stomach, or into the peritoneum, reveals the true state of matters. In the last case the result is generally fatal; in the former sudden exhaustion, amounting to collapse, may accompany a discharge of pus, or suffocation from effusion in the lung may prove fatal. The amount of pain depends on the part of the viscus implicated. If the matter be deep-seated in the parenchyma, at a distance from the peritoneum, the pain is comparatively slight or absent. If it approach the surface, or commence there, the pain may be severe. In any case there is a sense of distress and uneasiness felt most distinctly when the patient turns on his left side. Decubitus on *either* side is often painful.

In many cases of hepatitis, the patient is suffering also from malarial cachexia, and is liable to recurrences of febrile paroxysms which render it doubtful whether the chills or rigors are due to this or to suppuration; where there has been no malarial fever, the chills or rigors may be so slight, or so mixed up with other uneasy sensations, as to have escaped notice, and the patient denies having had them at all.

Again, if the abscess be small and central or posterior, the pressure is so slight on surrounding parts that the stomach is not affected, neither is pain felt in the right shoulder, nor uneasiness in the left side in the recumbent posture. In such cases the patients are apt to be regarded as suffering simply from general deterioration of health, disordered stomach and bowels, and congested liver from malarial cachexia, until the true nature of the case is revealed by the occurrence of the symptoms I have just described, or when, after death from diarrhœa, exhaustion, or other cause, it may be discovered that either an encysted and quiescent abscess still exists; or a certain amount of caseous matter in a contracted cavity shows that an abscess had formerly existed, but has undergone a process of drying up; or after years of broken health fresh inflammation may light up suppuration in or around an old abscess, and prove rapidly fatal.

The following cases will illustrate the subject under consideration:—

CASE 2.—An English officer, aged twenty-nine, was exposed, on military duty, to the fierce July sun in the north-west of India during the greater part of an afternoon. This was followed by severe headache and general malaise. A few days later he felt severe pain in the right side, and was placed under treatment. Three days later, on the 16th, the pain increased, and he had fever; leeches were applied over the liver. In the evening he had a rigor. During the next few days the pain increased; he had more leeches, aperients, and salines. The acute gave way to a diffused pain and weight in the hepatic region. Blisters were then applied. A swelling made its appearance four inches from the spine, below the ribs. He was then sent to Calcutta, where I saw him on the 4th September. He was weak and anæmic, with a yellow tinge of the skin. The liver was enlarged, and just below the last rib there was a fluctuating swelling. Pulse 100; skin cool and moist; no pain, but uneasiness and a sense of fulness in the side; breathing slightly embarrassed. His tongue was clean; bowels rather costive; appetite fair. I opened the abscess, and drew off through a cannula eighteen ounces of thick dark-coloured pus; the cavity was washed out with a solution of carbolic acid, one drachm to a pint of water. The cannula was left in the wound; the cavity yielded eight ounces of pus in the evening, and was again washed out with the carbolic acid and water.

Sept. 6th.—Drew off eight ounces; removed cannula, as it was causing irritation. There was no fever, and he was much relieved; the pulse less frequent. An aperient was given, as the bowels were confined. The wound was kept distended with a plug of lint soaked in glycerine and carbolic acid. Takes food and bitter beer with appetite. Quinine and sulphuric acid ordered; bowels to be kept open with sulphate of magnesia. Pulse 88; no fever.

8th.—Doing well, the quantity of pus daily diminishing; in the morning six ounces, evening two ounces. Eats and sleeps well; is in very good spirits.

9th.—Continued to improve. Two ounces of pus drawn off this morning; half an ounce in the evening. No fever. Pulse 78 to 84. Appetite good. The saline aperient to be repeated when bowels are confined.

10th.—Half an ounce of pus this morning; a quarter of an ounce in the evening. The cavity is evidently contracting. Pulse 74. He looks better.

11th.—Was fatigued by preparations for a sea voyage. Three-quarters of an ounce of pus in the morning; about one drachm in the evening. Pulse slightly quickened. He sailed this morning for England.

A report came from Ceylon that he was well enough to go on shore for a walk.

This is a good example of simple abscess of the liver in a young man of steady and regular habits. There was no history of dysentery or diarrhœa; it apparently commenced by congestion, terminating rather insidiously, as so frequently happens, in suppuration, which probably commenced about twelve days after the first symptoms of congestion. As inflammation approached the surface, the pain increased, and peri-hepatitis caused adhesion of the right lobe to the parietes. There was reason to believe that the abscess was solitary, and not due to septic absorption from dysenteric ulceration. The prognosis was favourable, as latterly the abscess had caused little constitutional disturbance. The rapid contraction of the cavity showed that repair was vigorous. Recovery proceeded rapidly under the influence of change of climate and sea air.

The following case shows the insidious manner in which liver abscess sometimes forms:—

CASE 3.—A young Englishman, aged about twenty-one, of fair complexion and healthy, vigorous frame, of rather irregular habits, after a residence of three years in Bengal complained of anorexia, hepatic fulness, general sense of failing health, disordered bowels, sometimes confined, sometimes relaxed; tongue loaded. He was anæmic, and the skin had a yellow tinge; tongue coated; pulse quickened. There had been neither rigors, chills, cough, nausea, nor vomiting. The liver was enlarged downwards, but there was no bulging, neither much tenderness on pressure. Saline aperients, to relieve the portal congestion, were ordered, and he was sent to sea for change of air; returned in a few days, and went to reside a short distance from Calcutta, continuing to perform his official duties.

When I saw him some weeks later he looked pale and thin, but was in good spirits, and at his work as usual; indeed he had not been absent more than a day or two. Though still weak, he was rapidly regaining strength. He informed me that one day, soon after his return from on board ship, after dining with some friends, one of them, in romping, accidentally gave him a squeeze by bending his body, which compressed his side. This was followed immediately by symptoms of collapse, with coughing and vomiting of a large quantity—a basinful—of purulent matter. A liver abscess had opened into the stomach, and evacuated. On recovering from the shock, he soon began to regain strength, and before very long was restored to health.

This case shows how insidiously the liver may suppurate without more marked symptoms than may be seen in cases of malarious poisoning, in which the general deterioration of health is expressed by occasional feverish attacks, attended by some hepatic congestion; the first evidence of the formation of matter being its sudden evacuation in the manner described. On the other hand, the most characteristic indications may have been present, including rigors, chills, high temperature, sweats, vomiting, with hepatic swelling and pain, and subside without any evidence that pus has formed; indicating acute congestion, which has resolved, or that an abscess may have formed and been removed by absorption, or have opened into the intestine, and passed

Digitized by Google

away so gradually as to be unobserved by the patient, who has regarded it as a phase of diarrhœa, from which he was already suffering. In fact, the diagnosis of liver abscess often escapes detection by the most acute observers.

Another case is that of an English officer, aged forty-two, of slight frame, but previously in good health, who had been in India several years, and returned to England suffering from symptoms of hepatic disease.

CASE 4.—"Col. R. B—— went to India in December, 1868. Since that time has spent twenty-one months in England. Returned to India in July, 1874. Up to this his health had been good. In the beginning of February, 1877, when at Mhow, he began to be ill. Pain sometimes severe on the left side of the back of the head; his skin became yellow; he was feverish, his spleen was enlarged, and the left side bulged; this was blistered and soon subsided. The pain in the head continued; he lost flesh, and seemed weak and ill. On the 27th of February he embarked for England. In Bombay he got worse, and on the voyage to Port Said was very ill—restless nights, intense weakness, loss of appetite, hands tremulous, shivering fits, and night sweats. He arrived in England on 2nd of April. He had had excellent health in India previously, and led a most active and very temperate life. He was at Delhi in December and January, in tents. Very hot days, very cold at nights. He used to be out all day, but was very careful in protecting his head from the sun. It was not until a fortnight after his return to Mhow that he began to complain of pain in the head—the commencement of this illness."

I found that the liver was enlarged downwards; his skin was tinged with bile, his face pinched and anxious, his urine occasionally loaded with lithates, bowels constipated; pulse from 100 to 120 and 130, very easily excited; great debility and nervous depression; walks in a stooping attitude and looks feeble; slight tenderness on pressure over the lower margin of the liver, no pain nor enlargement of the spleen; other organs apparently normal. The morning temperature was 100° to 101°, but rose in the afternoon to 102° and 103°. The general aspect was that of one suffering from hepatic suppuration.

I watched this case with much interest for several weeks, during which the progress was slow but satisfactory. There was gradual return of strength, less nervous depression, improvement in the condition of the urine and secretions, and a steady decline of temperature from 103° to 100°, and 99° to 98°, especially when he was under the influence of five-grain doses of quinine and hydrochlorate of ammonia, a valuable remedy, for the use of which in liver disease we are indebted to Dr. Stewart, B.M.S., taken three times a day. Pulse gained force, slower and less irritable; appetite, spirits, and the general aspect of convalescence gradually increasing.[1] It is impossible to say whether suppuration had taken place or not. A small abscess may have formed, that either had become quiescent and was gradually drying up, or may still some day reveal itself through the bowels, if it had not already done so unobserved.

The thermometer is, perhaps, the best indication of the changes going on in the liver, and the absence of other marked symptoms makes it difficult to form a diagnosis. One can only wait and watch the tide of daily temperature, pulse, and the state of the excretions. The continued depression of health, and the persistence of high temperature in such cases, especially if accompanied by chills and sweating, even though slight, point to suppuration; and it must be remembered that pus *may* become encysted, quiescent, and so localised as to have little or no apparent disturbing effect on the general health, and yet such a condition is fraught with danger from any accession of inflammation in the cavity or its vicinity, and the consequent increase of the primary abscess, or the development of new ones. Hence the importance of great care on the part of those who have suspected liver abscess, and the danger of exposure to any cause, climatic or dietetic, that might tend to set up fresh mischief.

CASE 5.—M. D——, aged twenty-three, came under my observation in Calcutta in April, 1867. He had been in Calcutta for about three years, had enjoyed good health until recently, and was neither intemperate nor irregular in his habits. On March 4th he had had ordinary fever, but when I saw him in April, though there had been no great amount of pain, there were well-marked indications of the formation of pus, but neither jaundice nor diarrhœa. The liver was enlarged downwards, and a prominence below the ribs was evidently due to an abscess. On the 19th of April I introduced a trocar and cannula, and gave exit to a large quantity of pus. The cavity was washed out with a weak carbolic solution, the cannula was left in, that more pus might be drawn off at intervals. He was much relieved, and soon improved. But to better his chances of recovery, and to get him away out of the intense heat of April in Calcutta, he was put on board a steamer, with the cannula still in the wound. He improved so much on the way home that it was removed before he reached Suez—"in about fourteen days." Within three months he had recovered, and ten years later I saw him in good health. He returned to India, and is, I believe, still there.

(To be concluded.)

[1] As I write, March 30th, 1880, he has come in to see me, having just returned from India. He looks in excellent health. Has had no liver trouble. Has recently suffered from renal calculus. Urine now healthy, except that it is rather phosphatic. It is interesting to note the occurrence of this calculus in reference to the damaged liver.

A NEW TREATMENT OF GONORRHŒAL OPHTHALMIA.

BY C. BADER,
OPHTHALMIC SURGEON TO GUY'S HOSPITAL.

GONORRHŒAL OPHTHALMIA, at all stages, is to the oculist a source of great anxiety. Whether local treatment—ice, bleeding, scarifying, caustics (all painful and often more than useless)—or general medical treatment (mercury, &c.), be employed, we meet cases, even if treatment be began at an early stage, in which the sight of one or both eyes is lost.

The treatment adopted in the following cases suggested itself by the fact that mercury, if thoroughly applied locally, has a destructive effect upon contagion. In vaseline, in itself of antiseptic origin, we have an invaluable means of bringing and keeping mercury in contact with mucous membranes, such as conjunctiva, urethra, &c.; daturin or atropin are added to counteract disturbances which, during the ophthalmia, may proceed from the iris and deeper parts of the eye. An ointment was employed, consisting of nitric oxide of mercury one grain, daturin one-fifth of a grain, vaseline one ounce.

CASE 1.—J. R——, aged seventeen (January 21st, 1879), suffers from gonorrhœa, ninth day. When seeing the patient with Dr. Wooley of Dalston, he presented all the symptoms of gonorrhœal ophthalmia in its acute stage. Eyelids of right eye blue, red, swollen, and so tense that only the lower third of the cornea could be seen; it was yellow and opaque; there was profuse purulent discharge. The left eye was healthy.

I considered the eye nearly lost, and felt justified, instead of the usual treatment, to try the effect of an ointment made of daturin and nitric oxide of mercury, of each one-fifth of a grain, vaseline one ounce.

I thoroughly washed away the discharge with tepid water, then with a large camel's-hair brush freely, though with difficulty, pushed the ointment beneath the upper eyelid of the right eye; this caused no pain whatever. Both eyes were then bound up with lint thickly smeared over with the ointment. The attendant was informed of the dangerous nature of the discharge, and was told to wash it away every third hour, and to apply fresh lint spread over with ointment to the eyelids of the inflamed eye.

For four succeeding days I applied the ointment myself beneath the right upper eyelid. On the third day the patient became slightly delirious, probably from the effect of the daturin. The mercury was increased to one grain, the daturin remaining one-fifth of a grain.

On January 30th I received the following from Dr. Wooley:—"The eye is very much less swollen to-day, but he has complained of severe pain. The delirium, which he was suffering from, has not returned, and he has made good progress.

February 1st.—Much better; ointment applied beneath the upper eyelid as before; fresh lint used once daily only; pus washed away repeatedly during the day; cornea visible throughout lower third, still opaque but not ulcerating.

3rd.—Eyelids again swollen with much pus. From this

Digitized by Google

day rapid progress was made. As soon as the eyelids opened freely, the application of the ointment with the brush was discontinued, and only lint and ointment applied every morning to both eyes. The left eye kept free from inflammation throughout.

March 5th.—Both corneæ clear; eyelids open freely.

I saw the patient once during the summer. He was completely cured; both corneæ clear.

CASE 2.—W. W——, aged three years and a half (November 6th, 1879), was sent to me by Dr. Ward of Finsbury Circus. The father of the boy, on inquiry, stated that the boy had slept with a servant who suffered from gonorrhœa. To admit of the treatment being carried out carefully, the boy was taken into the eye ward, Guy's Hospital. On admission the left eye was sound, the right suffered from acute gonorrhœal ophthalmia (eyelids red, tense, swollen; much chemosis, with conjunctiva protruding, profuse purulent discharge). On examination under chloroform only the lower third of the cornea could be seen; it was clear, with the surface softening along the margin. Portions of the conjunctiva of the lower eyelid were covered with a grey opaque substance, as seen in mixed cases of diphtheritic and purulent ophthalmia.

The pus was thoroughly washed away with tepid water. The ointment, with a large camel's-hair brush, was well pushed between the upper lid and the eyeball, and thickly applied to the conjunctiva. Both eyes were kept bound up with lint thickly spread over with the ointment. Fresh lint was applied every morning. Every third hour during the day the discharge was washed away with tepid water (the left eye being bound up), and the ointment pushed beneath the upper eyelid. This caused no pain, and the boy bore it quietly. On the third day the grey covering had disappeared from the conjunctiva.

On Nov. 13th the application of the ointment beneath the upper lid was discontinued; the lint was changed every morning, and the lids cleansed with tepid water.

Nov. 17th.—The eyelids open well; the conjunctiva is still congested; the cornea smooth and clear.

28th.—Discharged cured.

CASE 3.—B. E——, aged seventeen, was admitted into the Eye ward on Jan. 13th, 1880. His medical man states, "The youth came to me ten days ago with the eye much in the same condition as it is now. He had a week's treatment with tonics and the daily dropping of nitrate of silver solution (one grain to an ounce). The boy suffers from gleet." The right eye was healthy. In the left cornea, near the outer margin, was a deep large ulcer near perforation; the adjoining cornea was infiltrated with pus; there is iritis, chemosis, swelling of eyelids, and slight purulent discharge.

The ointment (atropin being substituted for daturin) was applied beneath both upper eyelids, and both were kept bound up with lint smeared over with ointment. This was repeated daily.

Feb. 3rd.—Much improved.

10th.—The patient was discharged. Right eye sound; left eye, surface of cornea smooth, outer third opaque, pupil somewhat irregular, fairly dilated. Was told to wear a shade, and to apply the ointment to the inner surface of the under lid at eight, two, and five o'clock.

CASE 4.—E. T——, aged twenty-six (Feb. 12th, 1880), was admitted with purulent ophthalmia of both eyes. Left cornea, small opacity near outer margin; right cornea, two opacities. Some iritis. Much chemosis and swollen eyelids, with moderate purulent discharge. The ointment was applied beneath the eyelids at eight, two, and five o'clock daily, and the eye kept bound up with lint and ointment. No pain whatever on application of the ointment.

Feb. 20th.—Patient was discharged with dilated pupils; smooth cornea, slightly opaque. All swelling of eyelids and conjunctiva had disappeared. She was told to wear a shade, and to apply the ointment to the inside of the under lids at eight, two, and five o'clock.

CASE 5.—B. S——, aged four (Feb. 20th, 1880); badly fed; has had whooping-cough for the last two months; cannot be admitted into the Eye ward. Both eyes are affected; the eyelids swollen, purple, tense, can hardly be raised. Conjunctiva highly chemotic. Both corneæ transparent, peeling along the margin. The ointment (nitric oxide of mercury and atropia of each one-fifth of a grain, vaseline one ounce) was, under chloroform, freely pushed between the upper lids and the eyeballs; both were bound up with lint smeared over with ointment.

Feb. 24th.—Judging from the size of the pupils, the mother, though shown how to apply the ointment, must have done so very imperfectly. The ointment, under chloroform, was again applied as above.

27th.—Same application under chloroform. All swelling of eyelids and conjunctiva has subsided. Corneæ clear and smooth.

ON MEDICAL CERTIFICATES OF INSANITY.

BY T. N. BRUSHFIELD, M.D.,
MEDICAL SUPERINTENDENT, BROOKWOOD ASYLUM, SURREY.

(Continued from p. 641.)

THE difficulty that medical men experience in framing a certificate is due to several causes, among which may be mentioned an imperfect knowledge of the nature and symptoms of the malady, and doubts as to which are the principal symptoms; but the prevailing difficulty appears rather to consist in the want of knowing the leading principles that should guide them in arranging and recording the "facts" they have ascertained.

Insanity is so protean in its character—no two cases being alike,—that all I can attempt to do is to indicate the principal division of symptoms that may require to be mentioned in the certificate, and to arrange them in the most simple and practical form. Undoubtedly the simplest form of division is into the three heads of the *appearance*, *speech*, and *conduct* of the patient; or, in Dr. Bucknill's words, "how he lives, what he says, and what he does." So that no point of importance might be omitted, I have elaborated this triple division into the following sets of symptoms. The arrangement is not a very philosophical one, but it will be found very convenient for the medical practitioner to bear in mind both in the examination of his patient and in the subsequent certificate.

Appearance.—Dress.

Speech.—Absence of speech, delusions, coherency or incoherency, memory, change in the higher emotions (speech), and other abnormalities.

Conduct.—Danger to others, danger to self, change in the higher emotions (action), propensities, general demeanour, and other abnormalities.

Appearance.—This does not, as a rule, receive its proper share of attention in certificates. It includes the general attitude of the patient as well as the facial aspect. The latter is often pathognomonic of some forms of the disease, and its description tends to strengthen the other recorded symptoms. For instance, what could be more expressive than "is of dull and heavy aspect" in a case of epileptic hebetude passing into dementia, or "facial expression of grief and dejection" in a patient suffering from acute melancholia. The wild and excited countenance in mania; the expression of pain and anxiety in some forms of melancholia; the dull, unintellectual visage, with averted eyes, in masturbation, &c., should all be mentioned. On the other hand, it is necessary to describe the kind of expression. Not only is this absent in the following certificate, but the whole of the symptoms taken collectively afford no proof of insanity, and yet the patient was suffering from acute hysterical mania: "Wildness and peculiar expression of countenance, numberless statements plausibly spoken as facts not having the slightest foundation in truth." Again, an entry like this: "She has the physiognomy of a patient with dementia," is of no value to anyone, since it does not describe the character of the peculiar physiognomy, and many sane persons would scarcely like to be declared insane on account of their demented look. Peculiarities of dress, especially when they show a marked change from the usual habit, should be recorded.

Absence of speech.—Some of the most difficult cases in which the medical man has to certify to insanity are those marked by obdurate silence, so that direct evidence is unobtainable from the patient's conversation. The symptom itself is an important one when allied with others. It may be owing to simple inability, as in some cases caused by sudden fright or shock; but in the majority of instances the patient can but will not converse. This may be owing to

Digitized by Google

general inertness, fatuity, hysteria, melancholia, simple perversity, &c. The certifier should endeavour to ascertain the cause, and, if successful, should state it. Unless the cause be known, a prognosis could only be guessed at. The following case was well investigated by the medical man, who was able to trace the silence to the existence of a delusion:—*Facts personal.* "The woman stares vacantly and stupidly at you when asked a question, but cannot be induced to speak, and appears to suffer from melancholia." The certificate was returned to be amended, when the following was added: "During the interview, which lasted a quarter of an hour, she continued to pace up and down the room, wringing her hands and groaning, but would reply to no question put to her." *Facts hearsay.* "Her husband informs me that for over a month his wife has rarely spoken, will not eat, appears quite indifferent to family and surroundings, and labours under the delusions that she has committed adultery, and that she has contracted venereal disease." This case was peculiar, inasmuch as the evidence of delusion rested entirely upon hearsay evidence. It was also a very instructive one, as showing how much a medical man can effect by making full inquiry into the whole history of the case, and stating the result of his investigation. The secondary testimony he obtained was of the greatest value in the subsequent treatment of the patient. The observations of the asylum medical staff corroborated those of the certifier. The patient had acute melancholia, from which she made a good recovery. She owned that during the period of her silence she felt frequently urged to commit suicide. The following certificate of one of this class contains a good example of motive-guessing when the patient would not speak:—"She has been before confined at Wandsworth on my medical certificate. She mopes about in a most melancholy way; will speak to none; will answer no questions; and obstinately refuses to take any food or do anything she is advised,—I imagine, as before, under a fear that she will be poisoned."

Delusions.—The larger number of cases of active insanity that fall under the notice of the medical men are characterised by delusions, and as they usually constitute the most important symptoms of the disease, I may be excused for devoting a little time to their consideration. The existence of a delusion not only at once demonstrates the patient to be insane, but simplifies the work of the medical practitioner in constructing his certificate. A well-marked delusion is of sufficient import to be detailed as one of the chief, if not *the* chief symptom exhibited by the patient, and which all the others relating to appearance and conduct will serve to corroborate. In a court of law a delusion is accepted as a proof of insanity. Many judges and eminent lawyers are apt to go a step beyond this, and to say that insanity cannot be proved without it, an affirmation that is not agreed to by psychologists, and if true would exclude a large number of persons who are now declared to be insane. To constitute an insane delusion the presence of cerebro-mental disease as a causation must be recognised. This at once excludes the false beliefs (sane delusions) which may pervade temporarily or permanently whole communities or nations.

Three classes of delusions as symptoms of insanity are recognised:—Hallucinations, illusions (delusions secondary), delusions proper (primary). The first two depend upon disorders of the special senses, but whereas hallucinations are subjective, illusions are objective. In hallucination there is false perception—a man fancies he sees or hears persons who have no real existence. In illusion there is a mistaken perception, a person, for instance, fancies the patterns of a wall paper to consist of live objects, another fancies he sees angels, where others notice clouds only. Both these conditions are perfectly consistent with acknowledged sanity, and so long as they are recognised by the individual who is the subject of them as sports of the imagination, he is considered as a sane person. Immediately, however, they are believed in as realities that no reasoning will disturb, they become, in this secondary condition, evidences of insanity, and are considered as delusions. Another class of delusions are of primary origin, and consist of an endless variety of false beliefs and ideas, not traceable to affections of the special senses. The legal term for all these conditions is simply "delusion," and I strongly recommend that this word be used in a similar sense by medical men, and so prevent the occasional confusion of terms in the certificate, of which the following may be cited as an example in which the patient, although the subject of hallucinations, was considered to have no delusion. "He appears to have no one positive delusion, but his mind is in a very confused condition, speaks of persons being secreted in and under the bed."

Insane hallucinations are much more frequent than illusions. Auditory hallucinations are of common occurrence, and yet medical certificates rarely mention them. The importance of their presence cannot be overrated, and their recognition by the medical man enables him to point out the probably unfavourable prognosis, and also to warn and guard against violence on the part of the patient towards others, and which he is prone to commit under the guiding direction of the imaginary voice.

If a patient entertains specific delusions, their nature and character must be recorded to make the entry valid. The sentences "full of delusions," and "continued restlessness and talking, with delusions," without further description, destroy the value of the certificates. Their insane character is sometimes so manifest that it is often thought unnecessary to call them "delusions"; as, for example, in the following certificate, where the first-named had the character of illusions and the latter of hallucinations. "She informs me that for several months past she has been accustomed to converse with birds, who frequently bring messages to her, and whose language she understands quite as well as she does mine; that she broke a pane of glass the other day for mischief; that the Almighty frequently reveals Himself to her in the shape of a dove, and that she is constantly hearing the voices of her mother and son conversing with her outside the door." But where their insane nature is not so apparent, and especially if they are possible truths, then it becomes a positive necessity to state definitely that they are "delusions," and indeed it is the more advisable plan to make this the invariable rule. A difficulty sometimes occurs where a medical man is assured that certain statements are delusions, and yet he is of opinion they are possible truths. If he is satisfied in other ways of the existence of insanity, it would be better for him to add, "I am informed these are delusions." I am not certain whether it would not be the wiser plan to add the name of the informant. In the following two examples the certificates were returned to the medical men to be amended, the subsequent additions proving the insane character of the patients' statements being added in each:—"States that his wife wants to poison him, and is following him about for that purpose"; addition, "this being a delusion." "Says that her daughter has been done away with—that last night she heard her screams whilst she was being murdered"; addition, "which statements are delusions." The imaginary ideas are sometimes reported by medical men as though they were absolute truths, as in this example: "Has written 'in his sleep' a large scroll, which is to make him immensely rich; he presents it to Lord Beaconsfield to-morrow; it will insure him the title of prince or emperor. Holds communion with spirits. He is to be the emperor over all nations." If these entries had been qualified—the first, for instance, in this form, "He informs me he has written in his sleep, &c.," and had added, "All these statements being delusions," the certificate would have been a very good and strong one.

A leading feature of a delusion is its remarkable persistency, in this respect contrasting strongly with the evanescent and variable character of the incoherent statements made in chronic insanity, or some of the extravagances uttered in general paralysis. That one is mistaken for the other, the two following examples will show:—"She is incoherently raving, and under the delusion that the woman next her is her sister." The case was one of acute mania, and the so-called delusion appeared to be an incoherent expression that was probably forgotten a few minutes afterwards. "The patient wants his legs cut off, ground, and cooked for breakfast—says that human flesh is a great improvement to his food." This case was one of confirmed general paralysis, and exhibited all the delusions of grandeur, &c., and exalted ideas so common in that disease. For instance, he declared his bones were made of diamonds, that he was strong enough to lift twenty tons, &c. The statement contained in the certificate was one of those extravagances uttered by general paralytics, but it was non-persistent, and in this differed from an ordinary delusion.

I append a few extracts from certificates in illustration of insane hallucinations, illusions, and delusions proper,

[1] The whole of Chapter 2 in Brierre de Boismont's work on Hallucinations is devoted to "Hallucinations co-existing with Sanity," and which contains a large number of examples. See also Dr. Blandford's article on "Auditory Hallucinations" in the Journal of Mental Science, vol. xix., p. 507 et seq. There appears reason to believe that all the instances mentioned were accompanied by a varying amount of cerebral disorder, not, however, amounting to insanity.

Digitized by Google

with a few short comments on each:—"Labouring under delusions—(1) when she has been walking the streets and looking at people they seem to change to the likeness of others; (2) although told that I am the medical officer she is under the impression that I am a person named George Grant, and continually asks the question 'Are you not George Grant'?" A good example of illusions of sight. "He says that he can see the root of all evil sitting on a beam in the ward." An unusual form of hallucination of sight. "I find him strange and incoherent in his language. He told me he had been in a trance forty days, and that he cannot go to his work because he sees dogs which terrify him." Hallucination of sight stated as if an actual truth. "Whilst speaking to him he fancied there were mice running about the room, that he heard burglars getting into the house, that different people whom he knew were coming through the door of the room, though it was shut, and he would stand up to salute them." A well-marked case of hallucinations of sight and hearing. "Talks in a hesitating and rambling manner. Says his head has been cut off, and stuffed with snakes; that his heart and liver have been taken out by men, washed, and put back again." This patient told me he could feel the adders moving about in his head; it appeared to me to partake more of the character of an illusion connected with the sense of touch than that of a delusion proper, under which latter term Dr. Blandford (p. 15) classed a somewhat similar case. The man was also the subject of auditory hallucinations. A good illustrative example of varieties of delusion in the same individual. "Does not believe her children are hers, and fails to recognise them when brought before her. Sees black men (natives) with white caps on at the foot of the bed, who disappear when she addresses them." An intermittent form of hallucination of sight, very uncommon. "She has a delusion that some one is continually, or almost continually, shooting poison into her body." An illustration of illusion of the sense of touch. On admission she confirmed the statement contained in the certificate—namely, the assertion that poison was shot into her by various things, such as a gun, telescope, &c., and that it felt like an electric shock. "Is incoherent and irrational in her language, and suffers from delusions; believes that her food is poisoned, and that she is informed of this by invisible means." A fairly common form of illusion of taste. "Her manner is very excited, and she has various delusions, one of which is that she has committed some heinous offence which is an unpardonable sin." A common delusion in some forms of melancholia. "He is under the delusion that he has lost all his bowels and inside, and is perfectly void of strength. Vacant countenance and expression. He says if he attempts to walk the wind gets into his legs, and he is blown away." "Very melancholy; fancies that he has starved his daughter, and that he is to be punished by being starved himself. Believes that his daughter is very ill in consequence of his treatment. She is in fact quite well and well off, and married, as he says, to a 'good fellow,' who is well able, and does take care of her." A good instance of an occasional form of suicidal melancholia, when the patient attempts to commit suicide, so as to avoid the consequence of an imaginary calamity. "That she is beset with delusions respecting the police having combined to persecute and annoy her. That wherever she goes the constables and detectives follow her. That they have taken lodgings in her house with similar views as regards her. That a constable inspecting a dog licence is a detective in disguise. That ordinary lodgers in the house are really police, &c. Her manner, aspect, and features show great nervous excitement, and she is exceedingly garrulous, incoherent, and discursive in her talk." This is a well-marked type of a class of cases of tolerably frequent occurrence, where the patient believes she is the victim of general persecution—that everyone is in a conspiracy against her. During her asylum residence she declared that all the staff, as well as the patients, were in league against her. Said they wanted to poison her food, &c. It appeared very odd for her husband to declare she was quite sane, and that her statements were true.

"Looks wild, talks incoherently, and told me he was in Deptford, although in Bethlem Hospital, and that Her Majesty has left him four millions of money, and also a publicanhas left him four millions of money, which is untrue." These grandiose delusions are commonly present in general paralysis, and are usually associated with exaggerated and exalted ideas of all kinds. In the instance just quoted the patient had all the ordinary symptoms of the disease. Taken by themselves these delusions are not pathognomonic of general paralysis, as the following certificate will show they may be present in other forms of insanity. The date of the certificate is Sept. 28th, 1860, and the patient, aged sixty-six, weak-minded from birth, is yet a hearty, healthy man, whereas, had he been a general paralytic, he would probably have died within two or three years after his admission. "He is in a morbidly-excited state, incoherent and threatening, fancying himself possessed of great wealth, legal knowledge, and the strength to vanquish any number of soldiers or constables, using threats of personal violence to his sister and neighbours." Loss of personal identity is a frequent symptom, of which the following are fair examples:—"At times he is perfectly silent, and will not answer, at others he is excitable, and says he is Jesus Christ." "Violent, incoherent, states that he is the Emperor Napoleon." The next two contain the whole of the entries in their original form; the first is obscure, the second invalid; both were returned to be amended:—"Irrational and sullen, and says and does the most irrational things, for which he can give no reason." "Very violent, and called me Dr. Kenealy; also saw objects in the fire."

Coherency and Incoherency.—The patient may be perfectly coherent and yet be the subject of delusions; these are the cases to which Locke's remark applies—viz., "Having joined together some ideas very wrongly, they mistake them for truths, and they err as men do that argue right from wrong principles." Swearing, violent, abusive, and obscene language may be as fairly coherent in the insane as it is in the sane when uttered under circumstances of great rage. In certificates these points should be stated for what they are worth, without the necessity of including them under the term of incoherence. Again, coherency of language is undisturbed in the simplest form of melancholia unattended with delusion, and also in cases of emotional insanity. Incoherency characterises two opposite forms of insanity—acute mania and dementia, but the causes are different in the two. In the former the flow of ideas is too rapid, in the latter there is direct failure of the mental powers. I will give quotations illustrating each condition. The first two were taken from certificates of the same patient (the subject of acute mania) by two medical men. 1st. "She is in a state of violent mania, rushing about, shouting, hallooing; threw her arms round my neck, and called me her saviour; that I was holy and pure, then she fell on her knees and began praying." 2nd. "She is in a state of raving mania, pacing round the ward in her chemise and raving incoherently." The next was a case of subacute mania passing into chronic insanity. "She talked incoherently and incessantly. She appears unable to talk about one subject, but branches off into a variety, and mixes one thing up with another." The last was a case of dementia. "There is evidence of confirmed imbecility both in appearance and speech. When accosted he is bewildered or confused, and answers questions at random or incoherently, and with hesitation. There is failure of memory and appreciation of common facts." Respecting the use of the term imbecility in this instance, it is better to restrict it to cases of congenital deficiency or arrest of proper brain development in early life, and to use the word dementia when the patient has once had his brain fairly developed, but its powers are in a state of decay.

It is often of the greatest use in certificates to mention the manner in which the patient replies to questions, giving an illustration where possible—whether he answers them coherently, incoherently, irrelevantly (as when his reply would have been a proper one to a totally different question), irrationally, by repeating the same word or phrase whatever the nature of the question, by repeating the last words of the question asked—like an echo.

Memory.—There may be a defect of the memory of past events only, or of recent events only, or of both. The memory of recent occurrences gradually fails as age approaches, and is more obvious in ordinary senile dementia, where the persons often appear to live, as it were, in a past world. In confirmed dementia following chronic mania or general paralysis, the failure is often very marked. The degree of defect or of failure should if possible be noted. In the following case the failure was not complete at the time of the patient's reception into the asylum, but became so soon afterwards: "She has an irritability of the skin common amongst insane persons, picking at and rubbing her skin. She has loss of memory, mutters incoherently, and

Digitized by Google

says she does not know what she says when she speaks." The allusion to the condition of the skin is noteworthy, as being on a par with the belief that existed a few years since as to the peculiar odour of the insane. I do not think that insane persons are more liable than sane ones of similar age to this irritability of the skin. When, however, it does exist, it is often made more manifest in the insane by their habit of picking it.

(To be continued.)

ON

VERSION, FORCEPS, AND THE EXPECTANT PLAN IN THE TREATMENT OF CONTRACTED PELVIS.

By WILLIAM T. LUSK, M.D.,

PROFESSOR OF OBSTETRICS IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; OBSTETRIC SURGEON TO THE NEW YORK MATERNITY AND EMERGENCY LYING-IN HOSPITALS; GYNÆCOLOGIST TO BELLEVUE HOSPITAL.

THE following remarks are intended to apply to the three most common forms of contracted pelvis only—viz., the flattened non-rachitic pelvis, the flattened rachitic pelvis, and pelvis equally contracted in all the principal diameters.

It is evident that the plans of treatment to be discussed are only admissible where the contraction does not exceed limits within which, under favourable circumstances, it is possible to deliver a living child through the natural passages. In most of these cases the appropriate treatment would be the induction of premature labour between the thirty-second and thirty-fourth week. But the physician may be first summoned after the end of gestation has been reached, or he may, at an earlier period, have decided against the induction of premature labour. At full term, supposing the head to present, the latter, at the beginning of labour, is prevented by the pelvic narrowing from entering the brim of the pelvis, and is usually freely movable. The conduct of the first stage of labour should be directed to preparing the way for the subsequent delivery of the child. To this end every pains should be taken to prevent rupture of the membranes before the cervical dilatation has become complete. The patient should be cautioned against restless movements in bed, and from leaning down during the pains. Examinations per vaginam should be made with great care, and should be avoided, except when absolutely necessary. The largest-sized Barnes's dilator, moderately distended with fluid, placed in the vagina to exert counter-pressure upon the cervix, is at times of use where the membranes have a tendency to protrude in the form of a narrow cylinder. Attention should likewise be directed to faulty positions and presentations of the child's head. Should these be dependent upon a pendulous abdomen, the fundus of the uterus should be elevated, and the normal relations of the uterine axis maintained by a suitably-adjusted bandage. Excessive lateral obliquity may be corrected by placing the patient upon the opposite side. Should transverse narrowing require a deep descent of the occiput, this can be furthered by placing the woman upon the side to which the occiput is directed. When, on the other hand, it is desirable to promote the dip of the forehead, the patient should be made to lie upon the side of the face. The reason of this is obvious, as, when the breech falls to a given side, the cephalic pole has a tendency to move in the opposite direction.

The right use of position as a corrective force depends upon the degree of accuracy with which the character of the pelvic deformity is estimated, and upon a proper appreciation of the mechanism appropriate to the ascertained deformity. When the sagittal suture looks forward toward the symphysis pubis, so that the posterior parietal bone becomes the presenting part, a firm compress above the pubis may be advantageously employed to press the head backward, and approximate the sagittal suture to the median line.

The pains, when weak and inefficient, should be strengthened by the warm vaginal douche; when the source of exaggerated suffering, they should be mitigated by morphia, by rectal injections of chloral, or by the administration of an anæsthetic.

Should, by good fortune, the rupture of the membranes be postponed until after completion of cervical dilatation, one of two contingencies may follow:—1st. The disproportion between the head and the pelvis may prove to be slight, so that a considerable segment of the cranial vault may be felt below the brim. Then, provided the head enters the pelvis in conformity with the mechanical laws dictated by the character of the pelvic deformity, the expulsion of the child may be left to the natural uterine forces. 2nd. No engagement may take place, the head continuing freely movable at the brim. Under such circumstances the disproportion may be assumed to be considerable. The physician has therefore to ask himself whether he shall await the action of the pains in the expectation that the head will gradually adapt itself to the pelvis, or whether he shall at once proceed to perform version, and drag the child rapidly through the straitened diameters. Forceps, as a means of delivery before fixation of the head, should be discarded, not because they cannot be employed with success, but because their use, even in the most skilful hands, is extra hazardous.

The question of waiting, or proceeding at once to version, is one that will always be decided largely by the individual experiences of the accoucheur. It is, however, vain to deduce rules of practice from the conduct of those who have enjoyed exceptional opportunities, and who usually have developed exceptional skill in some one special direction. It is to be remembered that in contracted pelves, in case the pains prove inadequate to overcome the obstacle to delivery, the alternatives in head-presentations are forceps and perforation. But there are very few experienced operators who have not a more or less personal predilection for either forceps or version, and this unconscious bias exercises necessarily, to some extent, a determining influence upon their choice. It is well known that there is hardly any subject which has been the source of so much heated controversy as the one at present under discussion. For the profession at large, however, there is little to be gained from the spirit of partisanship. The general practitioner not only requires instruction in the special advantages possessed by each measure, but needs to have presented to his attention parallel statements of the dangers and difficulties from which neither procedure is free.

In considering the application of version to the treatment of contracted pelves, it is well to state in advance certain points which are rarely alluded to, probably because they are matters of tacit agreement between the contending parties, to whose disputes we mainly owe our present knowledge in relation to the subject. The first of these is that the intent of the operation is to save the life of the child. In the case, therefore, of a dead child, or of one in which the heart sounds have notably begun to fail, version affords no advantage over perforation. For the same reason the conditions must be such as to hold out a reasonable hope of rapid delivering of the child's head without the infliction of necessarily fatal lesions. Now, there does not appear to be any well-authenticated case of the delivery by version of a full-time living child through a flattened pelvis measuring less than two inches and three-quarters in the conjugate diameter. But even with three or three inches and a quarter, the result will still depend upon the length of the transverse diameter. Thus, in extreme degrees of the justo-minor pelvis, with the reduction of nearly an inch in all the diameters, the difficulties of delivering the after-coming head, even with the aid of the perforator and the cephalotribe, are wellnigh insurmountable. Again, the contraction should be limited to the pelvic brim, for where the contraction is continuous or progressively increases toward the outlet the fate of the child is not even doubtful.

The other point of importance is that with three inches and a half and upward in the conjugate no interference in the rule is called for. Since it has become the custom to measure pelves with accuracy, the profession has learned that these moderate degrees of deformity exercise their influence not so much in a mechanical way as in the modifying effects they produce upon labour. A large proportion of the cases terminate spontaneously. If the pains fail prematurely, the conditions are generally such as to make it an easy matter to deliver with forceps. Difficulties only arise where the head is unusually large and incompressible, or in faulty positions, such as the anterior dip of the head in justo-minor pelvis, and the presentation of the posterior parietal bone in the flattened varieties.

Digitized by Google

Thus version is indicated in contracted pelvis only when the child's heart beats with nearly unimpaired vigour, and in pelves measuring between two and three-quarter and three and a half inches antero-posteriorly, with the contraction limited to the brim, and with sufficient amplitude in the transverse diameter.

The advantages of version in contracted pelvis grow out of the unquestioned fact that the after-coming head passes more readily the contracted brim than the normal head-first presentation. This superior facility is attributable to the entry of the head by its smaller bimastoid diameter. At the same time, the fronto-occipital descends in the transverse diameter of the pelvis. The pressure of the conjugate is encountered by the bitemporal diameter of the child's head, which measures half an inch less than the biparietal. Tractions upon the trunk of the child bring to bear simultaneously pressure upon the head from many points in the pelvic walls. As a result, bilateral flattening is effected, and a deep groove, usually near the coronal suture, is produced in many cases upon the posterior cranial surface by the pressure of the projecting promontory. The bulk of the head is still farther diminished by an over-riding of the bones at the sagittal suture, and, where the transverse diameter is insufficient, by the crowding of the occipital beneath the parietal bone. A reduction of the cranial contents is brought about by the retreat of a considerable portion of the cerebro-spinal fluid into the spinal canal. All these changes are induced rapidly, and are not dependent upon the activity and strength of uterine pains.

The method of performing version and extraction in contracted pelvis is, with few modifications, the same as in pelvis of normal size. In contracted pelvis great care requires to be taken lest the arms become reflected upward to the sides of the child's head, or crossed upon the neck. To avoid this difficulty it is desirable to introduce the hand over the abdomen of the child, and bring down the arms before the engagement of the shoulders. In delivering the head, traction may be made upon the lower extremities and shoulders, according to the method of Kiwisch, or traction may be made with one hand upon the shoulders, while two fingers of the other are inserted into the child's mouth. Provided by either of these methods the relation of the head to the shoulders is such that no twisting of the neck takes place, the amount of force that can be employed without producing fatal lesions is often something astounding. Thus Rokitansky, experimenting with the bodies of still-born infants, found the utmost strength put forth by two men upon the trunk insufficient to cause rupture of the vertebral ligaments and separation of the articulations. It is usual, however, to combine pressure from above, exercised by a skilled assistant upon the head through the abdominal walls, with tractions from below. Schroeder[1] states that this practice is coeval with podalic version. It was known to Celsus, and recommended by Ambrose Paré. It has found warm advocates in Pugh, Wigand, Martin, Krestellar, and, in this country, in Tayler and Godell. Both the latter gentlemen have made valuable suggestions regarding the technical management of difficult cases, which are well worthy of special mention. Dr. Tayler at first draws the body directly backward, while the head is forced by supra-pubic pressure downward and backward into the pelvis. So soon, however, as the head begins to advance, he raises the body of the child, and directs pressure upon the head to be made downward and forward in the axis of the outlet. In case of failure or delay he has sometimes succeeded by intentionally directing the back of the child to the sacrum, and then causing the occiput of the child to be pressed downward and backward into the nearest sacro-iliac space, with the face looking upward, while traction is made in the axis of the outlet. Dr. Goodell, after first drawing in the direction of the outlet, with the assistant pushing downward and backward, reverses the direction, and sweeps the child's body backward upon the coccyx, the neck likewise being forced downward and backward into the hollow of the sacrum with all one's powers. Where the projection of the promontory is not very marked, he likewise recommends, as something of assistance, a pump-handle movement, the range of oscillation extending from the axis of the outlet anteriorly to very firm pressure on the coccyx posteriorly.

(To be concluded.)

TREATMENT OF NÆVUS.

BY BENJAMIN WALKER, L.R.C.P.

THE following two cases of nævus are thought worthy of record, being interesting from their situation, and from the difficulty of treating them by the old method of ligature or suture, which were fairly tried and failed, and from the facility with which they were cured, one by the sodium ethylate of Dr. Richardson, the other by the actual cautery.

Laura L——, aged thirteen months. Nævus over right parotid gland, in size from half-a-crown to a crown piece; skin has a pinkish-blue mottled appearance, and is involved in about one-half its extent. The growth is prominent, and increases in size on crying, it is also gradually getting larger. On August 27th, 1878, it was operated on by wire ligature, previously transfixing with needles, and again on Sept. 9th and Nov. 6th, but without arresting the progress of the growth. On Nov. 12th sodium ethylate (of one-half saturation) was painted over it, and the application repeated three times in the next fortnight, and five times more at intervals of a month or two, till on August 3rd, 1879, the nævus was practically cured, the only marks perceptible being from the surgical interference (the entrance and exit points of the needles); had the ethylate been used from the first there would have been none, and its application is attended by little or no pain. To Dr. Richardson we are indebted for a most valuable addition to our armamentarium.

William B——, aged five months, a child at the breast, was brought to me on August 28th, 1878, with a nævus of the upper lip, involving the mucous membrane, and extending to the gum over the site of the incisors; skin not involved. It gave to the child a pouting and prominent upper lip, and was increasing in size, so as to interfere with prehensile power at the breast, and the child was beginning to fail in its nourishment. On August 28th it was operated on by transfixion and ligature, and subsequently by sutures on Sept. 9th and Dec. 17th, but it was most difficult to secure the whole by either method, and the nævus rapidly increased in size. On Dec. 25th the child was placed under chloroform, and the actual cautery applied pretty deeply into the growth in two or three places. Slough separated in a few days, and has left a perfect lip without any disfigurement.

Spondon.

CASE OF POISONING BY OXALIC ACID.

BY CHARLES FAIRFAX NURSEY, L.R.C.P. EDIN. &c.

ON the 7th January last I was called to see a woman, aged twenty-eight years, who had taken poison. I obtained the following particulars:—The patient had been drinking very heavily since Christmas-day, and to such an extent that on the day she took the poison she was bordering on delirium tremens. She left home on the morning of Jan. 7th and purchased in the town exactly half an ounce of oxalic acid, which, on her return at 9.30 A.M., she dissolved in warm water and swallowed. She vomited immediately and went to bed, where she remained vomiting in much agony until she was discovered by a neighbour at 1.15 P.M., lying on her side nearly dead. Fortunately the neighbour recognised her dangerous state, and obtained from her that she had taken oxalic acid. So he cleverly gave her carbonate of magnesia in water until my arrival, which was at 1.30 P.M., exactly four hours after swallowing the poison. She was then almost in a state of collapse; little or no pulse; just able to say that her throat and stomach were on fire. There was constant vomiting, tinged with blood; and cramps and numbness, with slight convulsive movements, in the limbs. The mucous membrane of the mouth and throat was entirely covered with a white coating, due to the corrosive action of the poison. As the patient could, and was only too willing to swallow, I continued the use of the carbonate of magnesia solution until she had consumed three or more pints of it, after which I gave her nothing but lime-water freely occasionally mixed with milk. Vomiting continued, and reaction set in. The body towards 6 P.M. became warm. Pulse returned, with slight colour in the cheeks. The epigastric and abdominal pain was severe, but the cramps slowly subsided. At 8.30 P.M. I gave up the lime-water,

Digitized by Google

and ordered ice to be sucked constantly, with an ounce of compound tragacanth mixture every hour in milk. In the morning I found my patient doing well, and, with the usual management in such cases, she was able in three or four days to come downstairs. During the treatment of the case I had the valuable assistance of my friend Dr. Dixon of Sunderland.

Remarks.—Considering the empty and inflamed state of the patient's stomach—the result of hard drinking—when she took more than a poisonous dose of the drug, and the length of time which elapsed before an antidote was given, it seems strange that she did not die long before any treatment was adopted.

KING'S COLLEGE HOSPITAL.

TRANSPLANTATION OF TESTICLE FROM GROIN TO SCROTUM.

(Under the care of Mr. WOOD.)

GEORGE D——, aged thirteen, was admitted on the 8th February last. When quite young a tumour was noticed in his right groin, which always disappeared when he was lying down, but reappeared when he walked about. He had worn a truss as long as he could remember. By this means he had always prevented the descent of the tumour till ten days ago, when it slipped past the truss, and could not be returned. Four days after, he experienced great pain in the right groin, the tumour increasing rapidly in size, with sickness and constipation.

On admission, there was found at the right external ring a solid tumour, irreducible, excessively painful, and with no impulse on coughing. There was absence of the right testicle from the scrotum. The diagnosis was—an inflamed undescended testicle. An ice-bag was applied, followed in a week's time by diminution of the testicle to its original size; it could not, however, be returned to the abdomen.

On Feb. 28th Mr. Wood exposed the testicle, which was found to be somewhat smaller than its fellow, by a vertical incision over the external ring. The cavity of the tunica vaginalis could not be found, and seemed to have been obliterated. The testicle, especially at its upper border, was attached to the pillars of the ring by very firm adhesions, which were with some difficulty broken down. Mr. Wood then freed the cord for about an inch and a half, and though he found it considerably shortened, by making traction he was able to bring the testicle down about an inch. He then everted the scrotum, stitched the testicle by catgut to the everted part, put a small drainage-tube in, sewed up the opening, and applied a pad firmly above the testicle, the whole operation being performed antiseptically.

The patient slept well on the night of the operation. Next day the testicle, though slightly retracted, was still well out of the external ring. There was no pain complained of, the wound united by primary adhesion, and the drainage-tube was removed on March 10th. The temperature was never over 99°. On March 15th the patient was discharged, wearing a water-pad truss, which was specially constructed to keep the testicle in the scrotum.

For these notes we are indebted to Mr. W. S. Miller, M.R.C.S., surgical registrar.

SAMARITAN FREE HOSPITAL.

CYSTIC SARCOMA OF BREAST; EXTIRPATION; NEUBER'S BONE DRAINAGE-TUBE; GOOD RESULT; REMARKS.

(Under the care of Dr. GEORGE GRANVILLE BANTOCK.)

A. D——, aged thirty-seven, single, was admitted on Nov. 26th, 1879. She had a cystic tumour of the right breast, as large as a turkey's egg, without any glandular enlargement in the axilla. The tumour affected the outer half of the mamma. She had also an abdominal tumour, which presented all the characters of an uterine fibroid. Its connexions were such as to forbid any surgical interference. The former, however, called for early operation, as the skin over the most prominent part was becoming very thin, and threatened early rupture. Menstruation came on two days after her admission, and it was not till Dec. 17th that she was ready for operation.

The tumour when first observed, about two years and a half before, was as large as a pigeon's egg, and was situated near the outer edge of the breast. It was then tender to the touch, but not painful. It had increased most rapidly during the last six months.

On Dec. 17th the tumour was removed, with the whole mamma, by two elliptical transverse incisions embracing the nipple. Three arteries were tied with silkworm gut, and the ends of the ligatures were cut off short. Compression forceps sufficed for other bleeding points. The wound was closed in its inner half (three inches) by a continuous suture, and in its outer by interrupted sutures, of silkworm gut. Before the latter were tied a bone drainage-tube nearly three inches long, about a quarter of an inch bore, and about half a line thick, prepared according to Neuber's instructions, was inserted. The operation was performed under phenol spray, but the wound was not washed out. The outer end of the tube was trimmed level with the skin; and, instead of the small safety-pin recommended by Neuber, it was secured by means of a piece of silkworm gut passed through it transversely, with ends two inches long. Next the wound, and over the end of the tube, were placed fourfold pledgets of thymol gauze, then alternate layers of thymol and carbolic gauze to the extent of probably twenty folds, and they were secured by a many-tailed gauze-bandage. Over this a thick pad of salicylic wool was placed, then Lister's eight-fold dressing, and again a many-tailed bandage, with shoulder-straps, also of gauze. As much discharge was not anticipated, it was thought unnecessary to follow Neuber to the letter in the matter of the dressing.

On the 18th, under the spray, the dressings were removed. There was very little discharge, and the wound looked as well as possible. The dressings were reapplied in the same order, with the exception of omitting the first bandage. Menstruation reappeared.

On the 24th the wound was exposed without the spray, and seen to be united throughout. There was not a trace of redness; only the gauze over the tube's mouth was soiled. The tube was quite fixed, flattened, and the presenting portion was dry and otherwise unchanged. The whole of the continuous suture, and two of the others, were removed. Vaginal discharge was very free.

On the 27th, with a view of ascertaining what was becoming of the tube, the wound was again exposed. The gauze was soiled to about the size of a shilling, just going through four folds. Another suture was removed, leaving the one next the opening. All the white and unchanged portion of the tube was cut away. Beyond this granulation tissue had invaded it. *In fact it had become organised.* The patient was allowed out of bed, although the uterine discharge had not ceased.

On the 30th the last suture was removed. No trace of bone could be seen, but a flattened body could be felt occupying the site of the tube, and it was evident that instead of melting down and coming away in the discharge it had become organised in its entirety.

On January 3rd there only remained a small granulating surface, less than the diameter of the tube. By the 9th it was quite dry, and the patient left the hospital on the 13th.

Remarks by Dr. BANTOCK.—In this country attention was first publicly called to the bone drainage tube by Mr. MacCormac in an address delivered before a meeting of one of the Metropolitan Counties Branches of the British Medical Association, held at St. Thomas's Hospital on Dec. 3rd last. Mr. Krohne had already shown me some of these tubes which he had made according to Neuber's directions, and on Mr. MacCormac's suggestion. I was then waiting for the time when my patient would be ready for operation, and I made up my mind to try the new tube so highly spoken of by Neuber, who is supported by Esmarch. Neuber cannot be said to have been in a hurry to proclaim his invention, for

Digitized by Google

it was not till he had observed thirty-six cases to their termination that he published his paper.

The following represents his general conclusions. He says that when a bone tube is put into a fresh wound in a good subject, no particular change is observable within the first twenty-four hours, but soon after that time the outer surface loses its smoothness and presents a worm-eaten appearance, and the thickness of the tube seems to diminish gradually under a slow melting process. In this way its solidity is so much impaired that by the fourth or fifth day it collapses under the pressure to which it is subjected. After six or seven days it is reduced to a pulpy gelatinous mass of more or less cylindrical form, and by the tenth day all trace of the tube has disappeared, except the part which is not exposed to the action of the tissues, and which is usually to be found loose in the dressings about this period. The rapidity of absorption varies in different individuals, depending on constitutional conditions and the state of the wound. In one case of amputation of the leg (to which he specially calls attention) in a patient much weakened by long illness, and the subject of albuminuria, the tube was not absorbed in fifteen days, although the wound had healed almost throughout by first intention. In another case of a more vigorous patient, after amputation of a large part of the scrotum, no trace of the tube could be found after the tenth day. He observed that the tube disappeared quicker in cases attended with discharge than in those without. He especially claims for his method that fewer dressings are required than with the ordinary india-rubber drain, and that it produces no irritation.

As far as my case goes I think I must admit both these claims. Had it not been for my anxiety to see how the tube was behaving, instead of exposing the wound on the seventh day, I might have left it undisturbed for a whole fortnight. So perfect has the healing process been, that the skin slips freely over the underlying tissues, and the tube moves with it. This indicates the only point of difference—viz., that after a lapse of twenty-six days the tube can still be felt, apparently of its original size, but flattened. Is it an unmixed gain that it has become organised instead of being absorbed or coming away in the discharge after having served its purpose? Still, on the whole, the result is very satisfactory. The lips of the wound at the end of twenty-four hours appeared to be perfectly glued together. Throughout the whole course of the treatment the patient felt nothing of her breast wound, and I am inclined to attribute the elevation of temperature on the second and third days, when it ranged between 99·6° and 100·4°, to the disturbance in the fibroid uterus. One of her usual periods had only just ceased a few days before the operation, and the same night the discharge returned, attended with considerable pain, especially for the first three or four days. All this time, however, the pulse was unaffected. In length of treatment this case does not compare favourably with the last case of the same kind, in which the tube was removed on the fifth day, and the healing process was quite complete by the eighth day. But of the two subjects the latter was certainly the more favourable for operation.

In the table of cases Dr. Neuber gives three cases of ovariotomy, of which two died (of peritonitis), and one recovered. The date of the first dressing in this case was the twelfth day. I do not hesitate to say at once that in this operation the bone-tube is wholly unsuitable, and that to use it is only to court disaster. In this case the principle is entirely different, and the peculiarities of the bone-tube are at once seen to defeat the object in view.

Dr. Bantock adds:—Since the above was written I have again used Neuber's tube—viz., in a case of irreducible hernia of omentum through the femoral ring, in which I unwittingly performed the radical operation for hernia introduced by Professor Socin of Bale. The case was rather obscure, as at no time while she was under my observation had any intestine descended. On the 17th inst. I cut down upon the swelling, and at once saw its nature. Completely isolating the sac, I then opened it, broke down an adhesion of the omentum, and tried to return it. As it resisted reasonable efforts I applied a ligature close to the ring, and cut away the omental mass. The stump at once receded. I then put a ligature around the neck of the sac, and cut it off. Both these ligatures were of silkworm gut, and the ends were cut off short. A small bone-drain was put in, and the wound closed by six sutures. On the 19th, the blood, which had escaped from the tube, had dried up in the gauze dressing, and the wound was quite dry throughout. On the 22nd, there was only a slight stain on the gauze just over the tube's mouth, and I cut away the end of the tube as close as possible, for this purpose pressing back the skin, so that the edges of the skin overlapped the tube. On the 24th, the skin had come together and united, and the healing was thus complete. On this day I removed the sutures. In this case also the tube was found firmly fixed at the first dressing, and its organisation was even then assured. It is still to be felt under the skin. There is reason to hope that this operation will prove a radical cure, as the ring was not stretched, and the ligatured neck will form a firm and resisting plug.

LEEDS GENERAL INFIRMARY.

CASES UNDER THE CARE OF MR. OGLESBY.

FOR the following notes we are indebted to Mr. Porritt, assistant house-surgeon:—

CASE 1. *Toxic effects after using strong solution of atropine.*—John A——, aged seventy, was admitted on the 6th of December, 1879, for the extraction of a cataract. He was a builder, and a strong, healthy man, who did not seem to be more than sixty years of age. A solution of atropine, containing two grains of atropine to the ounce, was at once ordered for the eye twice a day, and nothing noteworthy was observed after its use. On Dec. 9th the cataract was extracted by Graefe's method. There was a friable cornea, but the operation was completed successfully, with, however, the escape of vitreous before the removal of the speculum preventing the removal of soft matter by the scoop. Solution of atropine (four grains to the ounce) was dropped into the eye, and the pads applied.

For three days after the operation the patient complained of no pain, but on the third day, Dec. 12th, the pupil was found filled with soft matter. There were iritis and redness of the globe of the third degree. The artificial leech was applied to the temple, and one ounce of blood taken away, and six drops of a solution of atropine, containing ten grains to the ounce, were ordered to be placed in the eye every third hour.

On the 16th the night nurse reported that he had passed a restless night. He complained that his mouth and throat were dry. The sound pupil was widely dilated, and no skin eruption was observed. There was a vacant expression in the face, and he was slightly delirious, but answered questions rationally. The atropine was at once discontinued, and two ounces of the compound senna mixture were administered. At 8 P.M. the delirium had increased; he was irritable and more restless. There was paralysis of the lower extremities, and on attempting to walk he fell forwards, and had to be supported by the nurse. The bowels having been well opened, an eighth of a grain of morphia was injected subcutaneously, after which the patient fell into a sleep which lasted until morning, when he awoke sensible and well.

In this case the solution of atropine was placed in the eye eight times, the quantity used being equivalent to one grain of the alkaloid. This strong solution of atropine has been used on many occasions without any untoward effects.

CASE 2. *Fatal toxic symptoms after using a weak solution of atropine.*—William J——, aged fifty-nine, of Hunslet, had an iridectomy performed on the left eye twelve years ago, as a preliminary to the extraction of a cataract. In the interval between the two operations he attended as an out-patient, and was ordered a solution of atropine containing two grains to the ounce. After he had placed drops of the solution in the eye three times, he felt giddy and sick. The sound pupil was largely dilated; violent vomiting came on; the pulse became feeble and small, and the extremities cold. There were dimness of sight and vertigo, but no delirium, and on visiting him he was found in a state of complete collapse. He was wrapped up in hot blankets, and stimulants were administered, but he did not recover from the effects of the atropine until three days after the symptoms first appeared.

Out of the very large number of cases which have come under the care of Mr. Oglesby where it was necessary to use a solution of atropine for ophthalmic purposes, the above-named cases are the only ones in which symptoms of poisoning occurred.

CLINICAL SOCIETY OF LONDON.

Acute Rheumatism with Multiple Embolisms.—Amputation in advanced disease of the Hip-joint.—Secondary Hæmorrhage from the Stump of the Thigh, with Calcarcous Degeneration of the Vessels.

THE ordinary meeting of this Society was held on April 23rd, Dr. E. H. Greenhow, F.R.S., President, in the chair. A remarkable case of multiple embolisms from endocarditis in acute rheumatism was read by Dr. Southey. A case of advanced hip-disease, for which amputation was performed through the joint, was communicated by Dr. Stokes, of Dublin. Davy's lever was employed to control hæmorrhage, and the case was successful. Another contribution of surgical interest was one by Mr. Cripps, upon secondary hæmorrhage, due to extreme calcareous degeneration of the arteries of the lower limb.

Dr. SOUTHEY read notes of a case of Acute Rheumatism with Multiple Embolisms. The patient, a widow, aged fifty-six, of nervous temperament, came under Dr. Southey's care at St. Bartholomew's Hospital, on the eighth day of an attack of acute rheumatism. It was the seventh attack, and she had been treated previously at the hospital for the same disease. On admission, there was general hyperæsthesia, swelling, and tenderness in right parotid region, painful swelling of left hand and knee. In addition to an erythematous blush the skin presented ecchymotic and purpuric spots over trunk and limbs. Temperature 102·4°; pulse 120; respiration 36. The præcordial dulness was increased, and there was a systolic apex murmur (which had been noted three years previously); fulness and tenderness of abdomen, with evidence of splenic enlargement. She was given fifteen grains of salicylate of soda every four hours, which was discontinued after the fourth dose, owing to the supervention of delirium On the eighth day the highest temperature was 100°, lowest 99°; pulse 108; respiration 42. She was less rational; passed urine involuntarily; the parotid swelling had increased. On the ninth day the temperature was 99·2° to 100°; pulse 128; respiration 52. There was drooping of the left eyelid and less restlessness and pain. Death took place on the morning of the eleventh day, the patient becoming rather suddenly comatose twelve hours before. The post-mortem examination was made by Dr. Moore. No pus in the affected joints; patches of recent embolic softening met with in corpora striata, left cerebral hemisphere, and left lobe of cerebellum; spinal cord normal; right parotid gland congested, not suppurating; the mandibular articulation not diseased; ecchymosis in the larynx, and œdema of lungs. There was universal adhesion of the pericardium, a calcareous patch existing over the right auricle. The heart was large, and its cavities dilated. The most notable feature was the occurrence of numerous minute embolic areas studding the endocardium on both sides. The muscular substance was granular. Mitral orifice of large size; the valve fringed by vegetations. The liver and kidneys contained recent infarctions of variable size, and the intestines presented numerous ecchymotic spots. Dr. Southey considered the case to be one of acute rheumatism *plus* ulcerative endocarditis, with embolisms of skin leading to purpura (he believed embolism to be generally the source of "purpura rheumatica"). He had noticed this tendency of endocardial vegetations to break down and give rise to minute multiple embolisms in old ague cases, but he had never before seen so extensive an embolic affection of the heart-muscle itself. The condition of the nerve-centres suggested that capillary plugging is one of the causes of hyperpyrexia.

Dr. STOKES (of Dublin) read notes of a case of Amputation through the Hip-joint, in which Davy's method of preventing hæmorrhage had been satisfactorily employed. The patient, a tall, muscular man of forty years of age, a shoemaker and sexton by occupation, was admitted on August 29th, 1879, with signs of advanced coxo-femoral arthritis. The disease dated from a fall on the hip sustained in the year 1846. The immediate effect of the injury subsided under treatment, and for five years he was free from any symptoms, but in 1851 another injury again evoked the disease, from which he suffered till 1856. He then took to bootmaking and remained well till in 1871. Tired of a sedentary life he became a car-driver. At the end of 1878 he was in hospital for seven weeks, having been thrown from his car and again injured the hip. In April, 1879, he was obliged to take to his bed. The slightest motion gave him exquisite pain, and when admitted he was worn out from pain and want of sleep. Pulse 120; temperature from 99° to 102°. There was much eversion of the foot, and great apparent shortening of the affected limb. Three sinuses existed on the outer side of the thigh, two passing upwards and one downwards; denuded bone could be felt through the former. There was a large bed-sore over the sacrum, and the man's condition altogether most pitiable. His urine had to be drawn off, and great distress was caused by evacuation of the bowels. He had no desire for food. The alternatives of excision and amputation were considered. Against excision were the chronicity of the case, the probably wide extent of bone disease, and the great exhaustion of the patient. On the other hand, there is only one record of successful amputation of hip for disease, and that in a child eight years of age. On Oct. 1st Dr. Stokes amputated through the joint, Lister's antiseptic precautions being rigidly observed. The circulation in the limb was readily and completely arrested by means of Davy's lever, which was combined with Charles Bell's method of raising the limb and applying a bandage over it. The operation was made with an antero-external and postero-internal flap, as in Mr. MacCormac's case published in the *Brit. Med. Journal* of Jan. 4th, 1879. A carbolised silk ligature was placed on the femoral artery, the other vessels secured by catgut. The case made uninterrupted progress towards recovery; the pulse and temperature were seldom above the normal, and the man returned home in December, and resumed the shoemaking trade. Dr. Stokes remarked that the wound was kept perfectly aseptic for eight days after the operation, all the sinuses having been well scraped and treated with chloride of zinc at the operation. Some diseased bone was gouged out of the acetabulum, and the specimen (exhibited) of the femur showed extreme necrosis of its upper end, almost the whole of the head being absorbed, and two small sequestra being detached from it. The compact tissue of the shaft of the bone was extremely thin. The absence of shock went far to confirm Langenbeck's view that loss of blood is the main cause of shock after operation. It was noteworthy that in the two successful cases of amputation of the hip in Dublin the lever had been used and Listerian precautions carried out.—Mr. HOWARD MARSH said the Society was indebted to Dr. Stokes for coming so far to give them the record of this interesting case, and to bear his testimony to the value of Mr. Davy's method. That method had now been tried several times and had been discussed by the Society; still it did not seem to have received sufficient attention. He himself was much impressed by this method on its introduction, because shortly before he had seen a patient die from loss of blood from the posterior flap. The hip was being amputated for secondary hæmorrhage after ligature of femoral artery for aneurism. Lister's tourniquet could not be applied because of the rapid breathing of the patient, who was in extreme peril at the time of the operation. Every care was taken to control bleeding from the anterior flap; but the patient sank, presumably from loss of blood from the posterior flap. Shortly after that, Mr. Marsh assisted at a case of amputation of the hip in a child, when the lever was used and with perfect success. At the previous discussion on this subject it was asked whether any dangers followed the use of the lever. He had not heard of any; but, of course, great care must be employed.—Mr. HUTCHINSON, speaking of the propriety of amputation in cases of very severe disease of the hip, said that his impression was that a certain number of very bad cases were lost from unwillingness to resort to amputation. He had four times performed amputation in preference to excision; in two cases with complete recovery, but two became the subject of amyloid disease. In one of the cases the operation was certainly the means of saving life—the patient, a young woman, being extremely emaciated from the long-lasting disease of the joint. She is now in perfect health. All the cases occurred prior to Mr. Davy's method being introduced; but Lister's tourniquet or Esmarch's bandage (in three cases) was applied. No ill result accrued from the apparently for-

Digitized by Google

midable procedure of tying an elastic band tightly around the abdomen. He did not use Lister's spray and gauze in these cases; but employed lead and spirit lotion, and washed out the wound with spirit. In another case he should adopt Listerism, but still none of the above cases suffered for want of it. Dr. Stokes acted most judiciously, not only in deciding upon the operation, but in undertaking it so promptly. Mr. Hutchinson knew of a case where the patient died during the delay occasioned by the friends demurring to the extreme measure of amputation before other opinion was sought.—Mr. MACCORMAC said that it was plain a certain number of cases of hip-disease called for amputation because there were cases of a severe kind, which did not get well after excision. There was a lad now under his care at St. Thomas's Hospital, who was sinking from the disease, for which excision had been performed, and who would have recovered if amputation had been permitted by the parents. Amputation of the hip was called for also in cases of large and rapidly-developing tumour of the femur—such as that one he had recorded to which Dr. Stokes had referred. The patient was in a condition of extreme hectic due to a rapidly growing sarcoma, and the amputation afforded immediate relief. As to the question of shock, Langenbeck, speaking chiefly of cases of injury, avowed his belief that no shock occurs, except from loss of blood. But although in this case of his (Mr. Mac Cormac's) no blood was lost, the aorta being controlled by digital compression, yet after the limb was removed the lad was in a state of collapse, and appeared almost as if dead. — Mr. BRYANT said, the question of preference being given to amputation or resection depended to a large extent upon the age of the patient. In the young resection was comparatively a successful operation; in the adult excision of the hip was almost always fatal. In the adult there was not much experience of excision of the hip; but in cases of extreme hip disease he quite felt with Mr. Hutchinson that perhaps surgeons were too timid of venturing upon amputation; and the case brought forward by Dr. Stokes would have a valuable effect in encouraging surgeons to interfere in cases of advanced disease in adults—cases where resection would be almost hopeless. He would add his testimony in support of the value of Davy's lever. He had used it in a case of amputation for tumour of the neck of the thigh-bone, Mr. Davy kindly applying it; and certainly not more than two or three ounces of blood were lost. Loss of blood was the chief element of danger in amputation of the hip. He was accustomed to cut down at once on the artery, and to secure it by twisting both its severed ends, and at the same time to apply a carbolised catgut ligature to the femoral vein before proceeding further with the operation. In the case of tumour he had mentioned, he was struck by the scanty loss of blood, especially from the posterior flap. — Dr. GILBART SMITH asked Mr. Mac Cormac whether the shock produced in his case might not have been due to the compression applied over the aorta affecting the solar plexus. — Mr. MAC CORMAC said the pressure was applied immediately above the umbilicus. He did not think it was likely to have exerted any injurious influence on the solar plexus. A very small amount of pressure sufficed to control the flow of blood. — Mr. PARKER said he had amputated at the hip, in a child thirteen years of age, for diffuse periostitis of the upper end of the femur. The femoral vein was plugged. Although there was perfect control over the arterial circulation, much venous oozing took place, to which he attributed the fatal result that ensued. So great an amount of venous bleeding was unusual, and formed a serious difficulty in the operation. Dr. Stokes's case was interesting in view of a recent discussion at the Society upon hip disease, for it illustrated a point he had then raised that portions of the epiphysis were often detached as sequestra. Had these sequestra being removed some time before, it was possible that the patient might have recovered without loss of his limb.—Dr. STOKES, in reply, thanked the members for their comments which endorsed the line of action he had taken. One of the reasons why amputation was not more frequently had recourse to, was the fear of fatal result following the operation, and, until the introduction of Mr. Davy's method, there was always a great risk of this from loss of blood. Seeing that the mortality after amputation exceeds 50 or 60 per cent., it was not unnatural surgeons should hesitate to have recourse to it. The interference with respiration was an obvious disadvantage to the employment of Lister's tourniquet or Esmarch's bandage for compression of the aorta—a disadvantage got rid of by the use of Davy's lever. He still believed hæmorrhage to be the constant cause of shock; but he did not remember that Langenbeck held it was the *only* cause. In cases of amputation of the hip the bleeding is mainly from the posterior flap, so that in this respect Mr. Bryant's case was exceptional. Had the case come earlier under his notice, and he had been satisfied of the existence of the sequestra, he should certainly have removed them. But he did not think their presence alone caused the disease, which was most extensive, and involved the acetabulum as well as the femur.

Mr. HARRISON CRIPPS read notes of a case of Secondary Hæmorrhage from the Stump of the Thigh, with calcareous degeneration of vessels. The patient, a sallow, emaciated man, sixty-four years of age, was admitted into the Royal Free Hospital in November, 1878, with a large ulcer of ten years' duration on the leg, which had rapidly increased in size, and assumed a fungating appearance. The femoral glands were only slightly indurated. The leg was amputated just below the knee by anterior and posterior flaps, and a circular incision through the muscles. In the attempt to ligature the tibial arteries they gave way, their walls being extremely brittle from calcification. Acupressure also failed from the same cause, and the vessels being now broken off deeply between the bones, Mr. Cripps was obliged to reamputate above the knee. The femoral artery was found to be less brittle than the tibials, and was ligatured. Twenty-eight days after the temperature rose, the stump became swollen, and an attack of arterial hæmorrhage occurred. Chloroform was given, and the femoral artery was cut down upon and tied in continuity by carbolised catgut. But at the end of the fifth week hæmorrhage took place from the seat of the second ligature. It was controlled by pressure kept up along the course of the vessel, from the end of the stump, by means of a specially-contrived pad. The patient, however, died from exhaustion four weeks later. The post-mortem examination showed general calcareous degeneration of the arteries; a clot filled the femoral artery as high as the profunda. Mr. Cripps remarked that, in the first instance three courses were open to him—viz., application of pressure along the course of the main vessels in the leg; or pressure over the main vessel in thigh; or amputation higher up. He selected the third course as not interfering with the blood-supply of the stump, and as admitting of acupressure if the ligature of the femoral proved unsuccessful. Then, when the secondary hæmorrhage occurred from the stump, he might have reopened the flap and attempted to secure the bleeding vessel, or have ligatured the artery in its continuity, or again amputated higher up. The last course was precluded by the reduced condition of the patient; and he only regretted that the plan finally adopted on the further recurrence of hæmorrhage—viz., that of pressure along the course of the vessel—had not been followed in preference to the ligature in continuity.—Mr. HEATH did not think it possible for a surgeon to be aware of the condition of the arterial walls before operating; and in dealing with those brittle arteries broad serrated forceps should be used to draw down the vessel rather than the sharp-pointed forceps which tore through the coats. Pressure would do much to control hæmorrhage provided it be fairly applied, and not made too low down. Seeing how long a limb may be left blanched and empty of blood without injury, there was no reason why pressure should not be maintained sufficiently long to insure the formation of a clot. The precept, *Nimia diligentia*, was as applicable in dealing with cases of hæmorrhage as in other matters; and he therefore agreed with Mr. Cripps that perhaps it would have been better not to have tied a vessel which was found to be so extensively diseased, but to have trusted to the effects of pressure.—Mr. BRYANT agreed with Mr. Heath that it was unwise to use sharp-pointed forceps in dealing with atheromatous vessels. But if such a vessel be seized with well-serrated forceps, by simple torsion alone and the breaking up of atheromatous material, there was much better chance of arresting hæmorrhage. He had now constantly adopted torsion for many years, and in that time had often employed it for atheromatous vessels, and felt sure that no secondary hæmorrhage would occur if no bleeding took place during the first few minutes, his practice being to leave the forceps on the artery for a minute or so after the torsion. Secondary hæmorrhage was due to ulceration of the vessel from the ligature, and therefore he pleaded for torsion. He had never had a case of secondary hæmorrhage after torsion. He endorsed what Mr. Cripps had said as to the mode of dealing with the secondary hæmorrhage, except that where he suggested re-

Digitized by Google

amputation; for, as Mr. Cripps himself had formerly shown, the bleeding in such cases is from the lower part of the vessel. Pressure along the vessel was therefore the surest measure to adopt.—Mr. MACCORMAC asked if the effect of position had been tried.—Mr. CRIPPS, in reply, said that, during the operation, the stump was raised up, but without any appreciable effect on the force of the bleeding. On the first two trials to tie the tibials he used the ordinary pointed forceps; but on the third occasion he tried to catch the artery by torsion forceps, but the vessel had receded too far back. Re-amputation was had recourse to because of the impossibility of arresting the hæmorrhage in any other way. Then afterwards, in dealing with the stump, he feared to employ pressure owing to the swollen and tender state of the limb, and resorted to ligature in continuity, seeing that there was no risk of gangrene ensuing. Still he believed that pressure above and below the bleeding point is the best means for arresting hæmorrhage.

The Society then adjourned.

EPIDEMIOLOGICAL SOCIETY.

AT a meeting of this Society, held at University College, Gower-street, on April 3rd, Sir Joseph Fayrer in the chair, a paper was read by Dr. G. B. LONGSTAFF, on "Some Statistical Indications of a Relationship between Scarlatina, Puerperal Fever, Erysipelas, and certain other diseases," of which the following is an abstract:—The reader of the paper described an application of the graphic method to the statistics of the causes of deaths in England and Wales published in the annual reports of the Registrar-General. He stated that by representing the death-rates as curves, and comparing together the annual fluctuations of these curves, he had been led to divide the causes of death in this country into four groups—(1) the diarrhœal group, being directly related to the heat of the summer; (2) the bronchitic group, having a similar relation to the cold of winter; (3) the scarlatinal group, under consideration that evening, and (4) a provisional group, comprising all the other causes of death not at present known to be much influenced by meteorological conditions. A large diagram was exhibited, showing the death-rates from pyæmia, puerperal fever, erysipelas, scarlatina, laryngitis, croup, diphtheria, cynanche maligna, quinsy, and rheumatism with disease of the heart or pericardium, all graphically represented by variously-coloured curves. All these curves exhibited more or less marked indications of four periods of epidemic fatality separated by periods of comparative quiescence, but some of the elevations were more marked in one curve, some in another. The curves of puerperal fever and erysipelas appeared to be almost identical, and those of croup and diphtheria were also very closely allied. The diagram showed very clearly the varied headings under which deaths from diphtheria were returned in the country at the commencement of the great epidemic of 1858-9. The curve of rheumatic fever was also closely related to that of erysipelas, a point reserved for further investigation. Dr. C. Minor, of the United States, had called attention in 1874 to the close connexion between erysipelas and puerperal fever, and Dr. Longstaff's examination of the fatality of these diseases in the eleven registration districts of England and Wales for the last twenty-five years furnished a strong confirmation of his results. In order to approach this subject from another point of view, a diagram was shown (copied by permission from a paper by Messrs. Buchan and Mitchell in the *Scottish Meteorological Journal*) in which was given the mean weekly deaths in London from the same diseases for thirty years. The results gained by a comparison of the curves in this diagram on the whole confirmed the result obtained by the reader of the paper and indicated in the diagram first referred to. Laryngitis, and to a less degree scarlatina, were exceptions. But, again, puerperal fever and erysipelas closely resembled one another, as did diphtheria and croup. The amount of rain in each year, as well as the number of rainy days, seemed to be closely related to all the diseases under consideration, but in an inverse manner. The relative dryness or wetness of different seasons of the year showed no very apparent connexion with the fatality from diseases of the scarlatinal group, but a year on the whole wet almost invariably corresponded with low mortality from several or all of the members of this group, whereas in very dry years epidemics of these diseases occurred. The notable fact being that the same rule does not apply to small-pox, measles, whooping-cough, or typhoid fever. The explanation would appear that rain acted as a purifier of the air, washing the poison out of it, though it was not apparent why it only removed certain poisons. In the opinion of the reader of the paper the facts brought forward suggested that the poisons of puerperal fever and erysipelas, as also those of diphtheria and croup, were identical, and that the multiplication of species in the classification of disease should be avoided as far as possible.

Reviews and Notices of Books.

Clinical Lectures and Essays. By Sir JAMES PAGET, Bart., F.R.S., &c., Serjeant-Surgeon Extraordinary to Her Majesty the Queen, &c. Edited by HOWARD MARSH, F.R.C.S., Assistant-Surgeon and Lecturer on Descriptive and Surgical Anatomy at St. Bartholomew's Hospital. Second Edition. London: Longmans, Green, and Co. 1879.

To the honest practitioner, no less than to the philosophical student of medicine, it is deplorable that the exigencies of medical professional life in these days should encourage or require the uncultured and inexperienced or the needy, the arrogant, and the ambitious to write much and often, while they almost entirely prevent the skilled, the learned, and the experienced from writing at all. Sir James Paget is a conspicuous victim of this unhappy dispensation. It is many years since Mr. Paget, by his famous Lectures on Surgical Pathology, opened up to his professional brethren the promise of many valuable and substantial additions to surgical literature. But this promise has never been adequately realised. In 1875—that is, after the lapse of nearly a quarter of a century—Sir James Paget, timidly, and not without an apology, republished a selection of his Clinical Lectures and Essays, most of which had already appeared in medical journals or in hospital reports. These lectures and essays were, as a matter of course, well received, and a second edition has been called for. As the preface announces, few changes have been made in this edition. Four lectures on Gout in some of its Surgical Relations have been added, and an essay on some of the Sequelæ of Typhoid Fever. The editor has, moreover, largely augmented the notes and index. The new lectures on Gout in its Surgical Relations are replete with wise and judicious clinical observations, the results of a long and varied experience. Speaking of some of the consequences of injuries befalling the gouty, Sir Jas. Paget warns practitioners against the use of arnica lotion in liniments or in other local applications.

"I am not sure," he says, "that it is useful in any case; but I know that in the gouty it very commonly produces what is called erysipelas, or severe inflammation of the skin, often with vesication, always with intense heat and pain or burning, often spreading far beyond the part to which the arnica is applied, and in this way much more troublesome than the injury which it is meant to cure."

We are told that all gouty persons repair injuries of their joints more slowly than those who are healthy, and that gout may be suspected when, in a person of middle or later age, an injured joint does not recover in due time. Many of the unmanageable cases of gleet following venereal gonorrhœa may also, it is stated, often be referred to gouty inflammation producing thickening and contraction of the submucous tissue of the urethra.

Not a tithe of the richness of these and the other lectures could be exhibited by any summary. To be adequately appreciated they must be read over and over again. We must, however, in parting, point out a statement that has been allowed to stand in the second edition—namely,

Digitized by Google

that in the operation for femoral hernia "the first incision may be *vertical in a line drawn straight down from the spine of the pubes*" (the italics are ours). Such an incision would be surely too much to the inner side of the hernia.

Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques. Tom. xxviii. PIL—POI. Directeur de la Rédaction Dr. JACCOUD. pp. 752. Paris: Baillière et Fils. 1880.

THIS volume contains seven large articles and numerous notices of subordinate subjects. The former include Placenta, by Eugène Marchal; Plaies, by J. Rochard; Pleura and Pleurisy, by Fernet and D. Heilly; Plomb, by Prunier; Pneumonie, by Lépine; and Poitrine, by L. Merlin. The article on Pneumonia is the longest in the book, and is very completely worked out. The subject is treated by M. Lépine under the following heads:—1. Acute lobar pneumonia, which has twelve pages of closely-printed bibliography appended to it, containing the names of upwards of 500 authors, sufficiently attesting the interest that this affection has excited. 2. Broncho-pneumonia. 3. Chronic pneumonia. M. Lépine pays a just tribute to the genius of Laennec. Laennec's description of pneumonia, both in regard to its anatomical and clinical features, he says, was made by the hand of a master, and notwithstanding the labours of his successors, has left little to be added. The chief fact that has been ascertained in regard to the first stage or stages of engorgement since Laennec's time is, that the alveoli are partly filled with red globules, and by large cells, containing from one to three nuclei. These cells are evidently modified endothelial cells. Yet it must not be considered that this is pathognomonic of inflammation, for it has been shown by Friedländer that similar modifications of the cells may be seen in other states, and especially in œdema. In the stage of red hepatisation the lung presents a granular aspect on section. These granulations are due to the infundibula, which are filled with masses of fibrin, and these masses can be separated by scraping the surface, and are then found to be nodulated on the surface, the projections representing the alveoli. On microscopic examination these masses are seen to consist of fibrin threads, with white and red corpuscles in their meshes. In the stage of grey hepatisation a section presents scarcely anything more than masses of white corpuscles, with here and there large cells full of fat granules and pigment molecules. The leucocytes appear, from the recent investigations of Buhl, to be derived not only from the blood by diapedesis, but from the lymph, and by proliferation of the connective-tissue cells. The frequency of pneumonia is extraordinarily great, averaging from twenty to thirty per thousand in all the great hospitals of Europe. In regard to the causes of pneumonia, whilst the author admits cold, or rather a chill, to be the most common one, he admits, in addition, exhaustion, toxic agents, local injuries, lesions of the nervous system, miasmata, and the previous occurrence of certain febrile conditions. The greenish colour of the expectoration is due, he finds, to the presence of biliverdin, as may be shown by Gmelin's test. As compared with that of bronchitis, the expectoration in pneumonia contains no alkaline phosphates, whilst salts of the expectoration in bronchitis contain from 10 to 14 per cent. In pneumonia, the expectoration is richer in soda than in potash, whilst the reverse is the case in bronchitis; and lastly, the expectoration in pneumonia contains 8 per cent. of sulphuric acid, whilst that of bronchitis only contains 3 per cent. The various sounds heard on auscultation are very fully given, and he notes that crepitation has not quite the diagnostic value that Laennec attributed to it, since Grisolle, Woillez, and others who have paid special attention to this point, have satisfied themselves that in many instances (eighteen times in sixty-three cases, Woillez), crepitation either did not occur at all or at a late period only. An interesting section is devoted to the subject of pulmonary ventilation in pneumonia. Under ordinary circumstances the air expired by a healthy man contains nine-tenths of the oxygen inspired—i.e., $CO_2 : O = 0{\cdot}9$, but in double pneumonia $CO_2 : O = 0{\cdot}59$; and when one lung only is attacked, $CO_2 = 0{\cdot}72$ to $0{\cdot}63$. An interesting point has been made out by Schülein in regard to the temperature in pneumonia, which is not only that the periphery is maintained at a very high temperature, but that the curve of temperature of the extremities follows that of the axilla; so that the pneumonic patient not only loses much heat, but loses that heat with a regularity that does not occur in any other febrile affection. Tracings are given both of temperature and of the pulse. The remainder of the article is worked up with exemplary care and minuteness. The subject of treatment commences with a reference to the expectant plan, which yielded Dietl, a pupil of Skoda, such excellent results in 1849, the mortality being only 7 per cent., whilst the mortality in those who were bled was 20 per cent., and in those subjected to tartarised antimony also exactly 20 per cent.; but it is pointed out that at a subsequent date (1854), notwithstanding the expectant plan was still thoroughly adhered to, the mortality rose to 20·7 per cent., whilst Wunderlich had a mortality of 27·5 per cent. and Leudet of 25—28 per cent. Although the various means of treatment generally adopted are mentioned, this part of the subject is discussed with much brevity. We have left ourselves no space to allude to the other articles, and especially that on the chest, which is exhaustive.

NEW JOURNALS.

WE have before us early numbers of several new additions to medical journalistic literature. The *Deutsche-Amerikanische Apotheker-Zeitung*, published in New York, but in the German language, is intended as an organ for "apothecaries, doctors, chemists, and druggists," the "doctors" being apparently thrown in promiscuously, the chief part of its contents being designed for the class of pharmacists. *El Jurado Médico-Farmacéutico* is a weekly journal of medicine, surgery, and pharmacy, published in Madrid, the first number of which has just made its appearance. Although not a new periodical, since it is already in the second year of its existence, the *Annals of the Anatomical and Surgical Society of Brooklyn* is little known in this country. It is issued monthly, and edited by Dr. Charles Jewett. The April number contains, amongst other articles, a lecture by Dr. Wyeth, on the anatomical reasons for dextral pre-eminence in man, and papers on the surgical treatment of facial neuralgia, on uterine tumours, and an interesting biographical sketch, by Dr. G. J. Fisher, of Colot, and other old lithotomists. The periodical is admirably printed. Another monthly American periodical began its existence with the present year, the *Independent Practitioner*, devoted to "Medical, Surgical, Obstetrical, and Dental Science." It is edited by Drs. Harvey Byrd and Wilkerson, and is published at Baltimore.

CITY OF DUBLIN HOSPITAL.—The trustees of this hospital have appealed for funds to carry on the work of the institution in an efficient manner, and without reducing the number of patients admitted to the wards. In 1875 the hospital received £1160 from the Sunday Hospital Fund, and in consequence the directors provided additional wards, improved the dietary, increased the number of nurses, and appointed a resident surgeon at a salary of £100. As, however, additional institutions shared in the Hospital Fund after 1875, the receipts from this source fell off, and the result has been that on the 31st of last December a debt was due of close on £2000. Subscriptions amounting to £589 have already been received, and we trust that the amount required will shortly be obtained.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1880.

NO reformers are more urgently affected by the new political situation than medical reformers. When the Parliament was dissolved three private Medical Bills were before the House of Commons, or rather before the Select Committee of the House. The authors of these Bills, or their chief promoters, were Dr. LUSH, Mr. ARTHUR MILLS, and Mr. ERRINGTON. No less than two of the three are out of the present Parliament. Besides this, Mr. WHEELHOUSE, another member of the Committee, whose proclivities were strongly in favour of medical reform, has not been successful in the recent election. These gentlemen had made themselves familiar with the question; and Dr. LUSH, in particular, had not only, by his successive Bills, shown the really urgent points in medical reform, but in the last two Parliaments, at one or two important junctures, boldly used his position to stop measures, promoted by strong Governments, which would most prematurely and inadequately have dealt with the subject. The absence of these gentlemen from the new House of Commons is a great disadvantage to the cause of reform. The whole disadvantage, however, is not yet stated. Mr. FORSTER, one of the most earnest and honest of public men, went into the investigation of the amendments needed in the Medical Act as seriously as any other member of the Committee. His position as a leading member of the Opposition might have supplied him with a plausible excuse for declining to serve on the Committee. But he not only consented to act, but to take the chair of the Committee in 1879; and in 1880, though he declined the responsibility of the chairmanship, he continued to take an active interest in the inquiry, and did actually preside at the sitting at which Professors GAIRDNER and STRUTHERS gave their evidence. It would be sanguine to expect Mr. FORSTER, in office, and as the Secretary for Ireland, to give as much attention to the amendment of the Medical Act as he managed to give last year while in opposition. We must be satisfied if he continues his personal interest in the question, and uses his great influence in the Government to induce it to appoint a new Select Committee to complete the investigation which is so well begun; and this much we, for our part, will confidently hope for from Mr. FORSTER. There is an idea in some quarters that the Committee, at its last sitting, recommended the closing of the inquiry. Nothing is more erroneous. The Special Report of the Committee, agreed to on the 12th of March, runs as follows:—

"Your Committee are of opinion that, in consequence of the approaching dissolution of this present Parliament, it is not possible to complete the evidence which bears on the Bills referred to them. That the Bills be, therefore, reported to the House without amendment, together with the minutes of evidence taken before them, and an appendix."

Here is the judgment of the Committee that the evidence taken by it was incomplete. We have only to remind our readers that the Committee was hoping, before the unexpected notice of dissolution, immediately to be favoured with the evidence of Sir WILLIAM JENNER, to show how incomplete the evidence is, and how important it is that the work left undone by the late Parliament should be vigorously commenced and completed by the new one. It would be strange indeed if so good a piece of reform, begun by a Conservative Government and heartily helped by several members of the Conservative party, were to be abandoned by a Liberal Government backed by an unprecedented Liberal majority. Such a course would be disrespectful to the Select Committee and to the witnesses examined by it.

The enemies of reform may fancy this a favourable break in the process of investigation, and they may be excused for hoping that their individual corporations, with their half-diplomas and one-sided examinations, will be granted an indefinite lease of life. We scarcely think that these bodies will themselves so read the signs of the times. If they are wise they will accept the inevitable, and join those who honestly and eagerly wish to put the entrance examinations of the profession on a more satisfactory footing, and to equalise them in the several divisions of the kingdom. It must not be forgotten that the present Government is committed to a conjunction of Boards as deeply as, or even more so, than the late one was, and that it has learnt by experience that this reform cannot be secured without a contemporaneous reform of the constitution of the General Medical Council. Under such circumstances we venture to hope that there will be no further resistance to needed changes, which are likely to be moderate and reasonable in proportion to the promptness with which interested bodies agree to them.

It only remains for medical reformers to agree to resume their work with vigour and harmony. It is scarcely likely that actual legislation will take place this year, but there seems no reason why the evidence should not be completed during the present session, and all be in readiness for an amending Bill in the beginning of 1881. We would urge upon all sections of medical reformers united action, with a view to secure the re-appointment of the Committee and the examination of witnesses conversant with the defects of the present Acts, the faults of the General Medical Council, and the shortcomings of the existing system of medical education and examination. The Parliament will soon be absorbed in great constitutional and political questions, and the best time for asking its attention to the useful but unromantic question of medical reform will be at the very beginning of its life.

IT must be confessed that the doctrine on which the practice of quarantine is founded is both plausible and seductive. It assumes the practicability of arresting the dissemination of infectious or contagious diseases by preventing for a time any communication between the sick and the persons who have been in direct or indirect, or even possible, association with them and their healthy fellows as yet uncompromised by exposure to any chance of the infection; also by laying an embargo upon and keeping apart for a longer or shorter time anything — goods, merchandise, carriages, ships, &c.—which might become a vehicle for the transmission of infection from an infected person or locality. The doctrine of quarantine, in fact, assumes the possibility of, and the practice aims at, shutting out *all* sources of

Digitized by Google

infection from a healthy community. Such shutting out at first sight appears to involve little difficulty, but it was comparatively early recognised in practice, if not in theory, that a presumed efficiency of quarantine was very much a matter of locality; in other words, that quarantine was more likely to be successful in seaports than in inland places, and in preventing the incoming of foreign infection, than in arresting the spread of infection that had already effected a lodgment or was current in a country. So it happened that in process of time quarantine came to be regarded as specially a maritime question, and in seaport towns only, as a rule, has the system taken a permanent form among measures of sanitary police. It is particularly in its maritime relations that quarantine has retained, and still retains, its hold upon civilised nations. On the sea-coast, and as against the importation of foreign infection, the doctrine as applied in practice should hold good, unless some egregious fallacy underlies it; for what more simple (in appearance) than the supervision and isolation of all vessels, passengers, and cargoes coming from places whence they may be likely to, or even may possibly, bring with them some deadly infection! Now this, as relating to a matter of observation, and as affecting not only maritime but also inland quarantine, is a question of experience, and this experience, as we read it in this country, teaches us that while the doctrine of quarantine theoretically considered may in a certain sense be right, it has hitherto been found impossible to carry that doctrine out effectively in practice.

So marked has been the failure of quarantine to arrest any considerable extension of infectious disease, such as plague, cholera, yellow fever, &c., that in 1848-49 the General Board of Health of this country used this failure as an argument to disprove the infectious nature of these diseases! It is now known that the failure arose largely from the impracticability, in countries where any activity of commerce exists, of closing all the avenues by which infection could make its way. Contraband of quarantine was one of the commonest incidents of attempts to enforce quarantine stringently, and may be looked upon as a normal complement of the system. Moreover, in all great extensions of disease the initial extension has generally occurred before the danger was anticipated, and the imposition of quarantine has taken place after the mischief which it was designed to avert had been accomplished. This was notoriously the case in the great epidemic of cholera which invaded Europe and the Western hemisphere in 1865. The fact here referred to throws doubt even upon the applicability of quarantine in islands and places out of the ordinary routes of commerce, and whose relations with the outer world are so restricted as to give more or less reasonable hope that they can seclude themselves. Putting aside the cruelties which too frequently attach to the system, and the follies which have characterised its administration, as not essential to it, and regarding quarantine simply in its medical aspects as a measure for arresting the spread of infection, the teachings of experience we hold to be overwhelmingly against its efficacy for this purpose. True it has been asserted that we owe the recent escape of Europe from a general dissemination of plague to the strict measures of quarantine put in force by the Russian Government on the Volga. It is not explained by the asserters how the earlier measures of quarantine established by the Russian Government against the Persian ports on the Caspian to prevent the spread of plague from Ghilan and Mazanderan to Russian territory by the sea-route, and even the suppression of traffic with these ports for a while, failed to check that spread. Still less is it explained in what fashion a system of quarantine effected its object when the disease of which it was sought to prevent the dissemination had practically ceased (as was the fact) before any measure of quarantine was adopted in the infected district on the Volga. Certainly the world hardly ever before witnessed so strange an example of epidemic lunacy as that which occurred upon the news being made public in the first week of January, 1879, that plague had appeared on the Volga. The disease virtually came to an end in the second week of that month, yet beginning with that week, and for several weeks afterwards, European Governments vied with each other in reviving obsolete methods of quarantine, maritime and inland, against the compromised country, and against the uncompromised countries of each other. Even the British Government yielded to the general infection of alarm, and, in its fear, under the plea of political exigency did not hesitate to announce the revival of our old quarantine law, and to traverse our public-health administration—in other words, to transfer the functions of protecting the kingdom from invasion of plague from the skilled medico-sanitary officers of our seaports to the unskilled fiscal officers of the Customs, and the mere routine procedure of the Quarantine Act! And so also of certain recent westerly movements of cholera, and their seeming arrest in the Gulf of Suez, it does not seem to have been observed that this conclusion is much wider than the facts justify.

Quarantine starts from the fundamental position of the desirability of arresting or limiting the spread of infectious disease. Of this desirability there cannot be a question; but quarantine has failed to bring about such arrest, and so far as it may have contributed to limiting the spread, this has not arisen from any peculiar virtue in quarantine itself, but from circumstances incidental to its exercise, and not necessarily connected with it. Much of the error still existing with relation to the assumed merits of quarantine arises from a failure to discriminate between those matters which are essential to the system and those matters which in recent years have become superadded to it. In so far as it has proceeded and still proceeds upon arbitrary lines of secluding the sick and the so-called compromised healthy, and of crude, incongruous chemical disinfections, quarantine has been and is an unmixed evil, not only from its futility, but more especially from its diverting attention from a true prophylaxis of infectious disease. In so far as it may have contributed to a clearer knowledge of the conditions under which the isolation of persons and things is desirable and may be advantageous, and of the hygiene of ships, and of masses of persons, such as pilgrims and emigrants, journeying both by sea and by land, quarantine may indirectly have yielded certain advantages, but advantages wholly disproportionate to the cost at which they have been gained, and which were attainable in a much simpler and more effective fashion. Quarantine, in fact, is but the perpetuation of a traditional practice which had its origin five centuries ago in the dark ages of physic, which is fundamentally unchanged notwith-

Digitized by Google

standing certain modern verbal veneerings, and which is inconsistent with our present knowledge of the habits of infectious diseases.

In this country and in Denmark, quarantine has for some time ceased to have a medical signification. It is retained on the statute-book, and ordinarily exhibited in certain formal administrative measures, to obviate disabilities which would else be imposed upon our shipping in the ports of Governments which adhere to the practice of quarantine. Here the general sanitary administration of the kingdom is so devised that every district, inland or coastwise, is enabled to deal with infectious disease, coming from whatever source, by removal of the conditions which would foster its development, by preventing reckless dissemination of infection, by isolation of the infected individual, and by disinfection. In addition and with reference to foreign infections, port sanitary authorities are given the power as regards cholera to medically inspect persons arriving in ships from infected places, to remove and isolate the sick found on board (letting the healthy go free), and to use such processes of disinfection as to the vessel and the articles thereon as may be deemed necessary. This method of dealing with foreign infection is founded not upon imaginative beliefs as to possibilities of infection, but upon actual observation of probabilities, and there can be no doubt that it is equally applicable to plague and yellow fever as to cholera. The method here referred to has been termed the system of "medical inspection" as contrasted with "quarantine." Experience shows that it does all that the most efficient quarantine can be hoped to do, and this more effectually, without involving those grave hardships to individuals and interruptions and disturbances of commerce which have arisen and must arise from quarantine. Quarantine having failed to *shut out* infectious disease, is thereby condemned; the *limitation* of infectious disease may be effected in other and better ways, of which the system of "medical inspection" is an example. It is not asserted here that that system may not be capable of amendment, but it is affirmed that, being founded upon actual observation and forming part of a method of dealing with infectious diseases, in view of their limitation, which obtains throughout the whole country, it has greater claims upon professional and public confidence than a system like quarantine, which is founded solely upon assumptions that have been discredited by experience, and of which the administration, with reference to disease prevention, is an insult to ordinary intelligence. It ought to be sufficient to condemn even the formal administration of quarantine in this country, that the quarantine (Customs) officer, not long ago, in one great port, questioning the master of a ship as to sickness on board, could pass the ship into dock with more than one person dead of cholera in it, and that the Customs' "rummager," whilst "rummaging" the same ship, could turn a man dying from cholera over in his berth without recognising the fact. Again, in another great port, about the same time, the quarantine officer, shouting out his questions to the master from his boat alongside, gave free passage to a ship with cases of cholera on board to be landed in the seaport town. And these are but samples of the sort of intelligence (!) which enters into the quarantine administration of English ports. It is derogatory to England that she should submit to continue hideously farcical, and, so far as the public health is concerned, highly detrimental proceedings such as these, to meet the unreasonable demands of certain Continental Powers; it is more than derogatory when real precautions can be substituted for sham ones—precautions of a nature which it is difficult to believe would not be accepted in lieu of obsolete quarantine arrangements by the Powers in question.

WE are instituting an inquiry concerning the hygienic conditions of school life, and the physical and mental training of the young in establishments, whether public or private, devoted to educational purposes for gain. It is important that the question should be carried into the class of schools, not always so called, conducted by clergymen and others who "take boarders" to educate "with their own children." We ask, and expect to receive, the cordial help of those who are engaged in this work, counting with confidence on the fact that a spirit of earnestness pervades the ranks of those who are engaged in the care and culture of the young, and therefore any new light which may be thrown on the principles of mental and physical education as an applied science must be welcomed as it deserves to be. In order to make the investigation really useful, the largest possible number of facts must be at our disposal, and the task of collating the data so obtained for the purposes of inference must needs be heavy and arduous. We shall approach the subject without prejudice of any kind, and it may be said at the outset that we do not expect to find any grave scandals or defects to be exposed. The days which permitted the system illustrated by that master of social caricature, the late CHARLES DICKENS, to flourish have gone; and although history repeats itself, Dotheboys Hall is not likely to be reconstructed, at least not on the old foundations. The faults of to-day are for the most part errors of judgment, or defects arising out of, if not due to, circumstances. There may be some lack of progress, but even this is probably the result of failure to recognise the importance of the issues involved rather than of indifference. In a word, we regard the profession of educators as composed of honourable and earnest workers; and it is solely with the desire to aid their enterprise, so far as the science of health and development is concerned in the care and culture of youth, we interpose.

The outline we have sketched for the guidance of those who are willing to give us their help in the preliminary stages of this inquiry, indicates as topics for the statement we are anxious to receive from every schoolmaster and educator the following questions:—1. How many boarders have you, and what are their ages, generally? 2. Were the premises now appropriated as a school-house built for that purpose, or adapted? What is the nature of the ground on which the building stands? Describe the locality, and give particulars as to climatic conditions. 3. What cubic air-space is allowed to each sleeper in the dormitories or bedrooms? 4. What is the size of the apartment used as a schoolroom, and how much cubic air-space is there for each pupil? 5. What is the ordinary diet, as to the quantity and kind of food, and how are the meals distributed? 6. What time is spent in school-work, and what hours are devoted *wholly to*

Digitized by Google

play? State the hours of retiring to bed and of rising, and mention the arrangements for visiting the sleeping apartments at unexpected times. 7. What cases of illness occurred in the school during the years 1878-9, and what has been the general state of health in the establishment? If any epidemic disease has visited the school, please state the circumstances. 8. What are the sanitary arrangements of the establishment as regards drainage, closets, lavatories, bathing, towels, brushes, &c. &c.? 9. What provision is made for the isolation of cases of infectious or contagious disease in the event of a *sudden* attack? 10. What system of medical inspection is adopted? Does a medical man systematically visit the establishment, or does the "doctor" only attend when called in to treat a case of sickness? Nothing depends on the precise terms employed, but, in response to the expressed wish of our correspondents, we offer this suggestion of points on which it is desirable our Commissioners should be at once informed.

We depart somewhat from our usual practice, in opening an inquiry of this nature, by addressing the responsible managers of the institutions it is desired to inspect, but the reason will be obvious to anyone who reflects on the magnitude and great importance of the undertaking to which we now stand committed. It would clearly be impracticable to visit a tithe of the smaller, but in a practical sense, the most important, establishments in the country; while no investigation of this class could prove of any great value unless it covered the whole field. The course we intend to pursue is simply this. Having ascertained how far the great body of teachers may be willing to take advantage of this offer of help in their work—which we shall be entitled to infer from the number and nature of the replies with which we are favoured—it will be incumbent upon us to consider in what light the reticence of those who are not disposed to regard the inquiry with favour ought to be viewed, whether, in short, their unwillingness is based on reasonable grounds. The proportion of refusals to co-operate will, so far as we can yet judge, be very small, and it may suffice to deal with the cases individually. Our sole object is to get at the *facts* relating to the education of the youth of this country, and to study the various systems of care and training which at the moment prevail. In the end, we propose to give the results of our inquiry in the form of reports and suggestions, with a view to formulate the conditions of health in body and mind, as definitely as may seem to be expedient. These results will be the mean of vast multitudes of experiences, tested by the methods which science creates and applies to the details of practical life. It will now be apparent how essential it is to secure the co-operation of all experienced educators, and to their known anxiety to do the best for the youth committed to their guardianship we now appeal.

AT the last monthly meeting of the Board of Management of the Manchester Infirmary it was stated that a sub-committee had been appointed to have an interview with a sub-committee of the Medical Board, in order to consult as to the desirability of the medical students paying something to the funds of the infirmary. It appears that hitherto they have not contributed anything towards the maintenance of the institution, although the whole of its appliances, instruments, &c., have been freely placed at their disposal.

Annotations.

"Ne quid nimis."

"A GREAT POLITICAL OPPORTUNITY."

UNDER this heading, in our issue of April 10th, we wrote as follows:—"The weak point in the English system of government as at present constituted, is the isolation of the department which *theoretically* gathers up the reins of local self-government and places them in the hands of the Ministry, but which *practically* not only fails to perform that necessary function, but entangles the ribbons and frets the team.....It is easy to cut the Gordian knot of this difficulty, and to render the process of reconstruction facile by the simple and timely precaution of placing a strong and wise man at the head of the Local Government Board, and making him a member of the Cabinet.....We have long and importunately insisted on the claims of the country to a Ministry of Public Health. *This need would be satisfied if the Minister upon whom it devolves to carry out the provisions of the Public Health Acts were a member of the Cabinet.* The immediate effect of such an arrangement would be to make the health interests of the country *an integral part of the Ministerial policy.* It could not be otherwise. And thus we should gain in fact what the country has been repeatedly promised in a figure of speech, a policy having for its maxim *Sanitas sanitatum, omnia est sanitas.*"

In no spirit of vainglorious exultation, but with sincere gratification, on behalf of the profession THE LANCET represents, we now record the fact that this policy has commended itself to the judgment of the Prime Minister, and has been carried into effect. Mr. Dodson, a statesmanlike legislator of tried ability, in whom the profession and the public will have the fullest confidence, has been appointed President of the Local Government Board with a seat in the Cabinet. It is only necessary to repeat that the step we recommended, and which has now been taken, "is certainly one which must have a keen interest for the medical profession and the country at large, because it will create a Ministry and give us a Minister of Health—a double boon, which political feeling and public expediency both urgently crave."

By this procedure Mr. Gladstone has, at the outset of his new career, established a strong claim on the respect and good feeling of the not unimportant medical services connected with Public Health and the Poor Law department, and given a practical pledge of reforms which are urgently needed, and could not, under any circumstances, be long deferred. It was a timely and sagacious measure to concede the recognition we have so long struggled to obtain. The path is now cleared of many difficulties, and the Government may count on the support of the medical profession on grounds broader and more permanent than any mere considerations of political sympathy, or party claims.

VACCINATION IN THE METROPOLIS.

A DIMINUTIVE, but suggestive, ray of light is thrown upon the defective administration of the Vaccination Act in the metropolis by a letter addressed by the Local Government Board to the Shoreditch Board of Guardians, and read at their meeting of April 14th. It appears that Dr. Stevens, one of the central authority's inspectors of vaccination, has

Digitized by Google

reported that the vaccination returns from Shoreditch are very low as compared with other metropolitan parishes, and that he attributes this shortcoming principally to the great bulk of the children born in the workhouse escaping vaccination. Dr. Stevens recommends that the Shoreditch Guardians should follow the example of the guardians of St. Pancras and St. Giles, Westminster, and give the medical officer of the workhouse a small fee for each child vaccinated in the workhouse. This recommendation is to be considered, and, meanwhile, the Shoreditch Workhouse is to be permitted to store up fuel for the next epidemic of small-pox. As we understand this question, the Local Government Board casts on the one hand the duty of vaccinating children in the workhouse upon the medical officer, but, on the other, it admits that this duty should not be thrust upon him except in consideration of some special remuneration for it. The guardians have a discretionary power in granting such remuneration. Thus it happens that the Local Government Board in effect deprecates the performance of his strict duty in this matter by the medical officer, and if, as in the case of Shoreditch, the guardians elect to be governed by the literal requirements of the Local Government Board's orders as to the duties of the medical officer, vaccination is liable to be very much if not wholly neglected within the workhouse walls. An anomalous state of things of this sort would have been hardly tolerable under the old poor-law administration; but now that the poor-law and public-health administration are brought together under one central authority, it is a public scandal that trumpery administrative difficulties of this kind, created by the central authority itself, should not be removed.

POPLITEAL ANEURISM.

THE interesting case of popliteal aneurism successfully treated by Esmarch's elastic bandage, showed to the Medical Society on Monday last, is one of the best results of this treatment yet obtained, and Mr. Goodsall must be congratulated upon it. The aneurism was a large one, had developed rapidly, and from all appearance had a very free communition with the artery—a large mouth to the sac. The treatment differed slightly from that hitherto employed, for the bandage and tubing were left on the limb for three hours—a very long time—and the bandage below the aneurism for an hour longer, during which all flow of blood through the artery must have been stopped. The treatment was really employed for four consecutive hours; for all that time there must have been complete stasis of the blood in the aneurism and adjoining part of the artery. When the bandage was removed the artery above was not subjected to compression, digital or instrumental, as has been customary, and no pulsation was at any subsequent time detected in the sac. In this case, therefore, there was rapid coagulation of the blood both in the aneurism and adjoining artery, which speedily resulted in complete cure. In many cases when the bandage has been removed pulsation has been much lessened, or even very slight indeed, and, under the use of digital compression, has gradually disappeared altogether. In these cases the clotting has at first only taken place in the aneurism, and the circulation in the still patent artery has transmitted pulsation to the tumour. When the force of the blood-current was diminished the clotting was enabled gradually to extend from the aneurism to the artery. In other cases, again, the pulsation, at first greatly lessened, has gradually increased to its original intensity; here the clot first formed has, in all probability, been gradually disintegrated. Mr. Bryant's case of popliteal aneurism which ran this course, in which gangrene of the foot supervened upon the case, confirms this view, for the gangrene is most easily explained by embolisms from the aneurism. Mr. Goodsall's case lends support to the view originally set forth by Mr. Gould in our columns that this plan of treatment is most successful in aneurisms with large mouths, in which the clotting readily spreads into the artery, for in his opinion the cure results from the plugging of the artery, and not from the filling of the aneurism.

THE REPRESENTATION OF THE UNIVERSITY OF LONDON.

THERE is now no doubt that the member for the University of London is to be raised to the peerage, and a vacancy will thereby be created in that constituency. Rumour has already been busy with the name of his probable successor in the seat; and it has been strongly urged by Dr. Joseph Rogers, in the *Times*, and also by Mr. Reginald Harrison, of Liverpool, in a letter to us, that the opportunity should be seized for securing a medical representative. No one can be more desirous than we are to see more representatives of the medical profession in the House of Commons, but when we remember that the medical graduates of the University form barely one-third of the constituency, it seems almost impossible for the University to be represented by a medical member, unless his claims be so great as to commend him to the whole constituency on other than purely medical grounds. Should such a candidate be found, he would prove a most desirable addition to the House of Commons; but so far as can be judged of the result of the recent election at the University, it seems clear that it would be a matter of great difficulty to secure a candidate from amongst the medical graduates who would find favour with the vast majority of the electors. The Master of the Rolls, Sir Julian Goldsmid, and Sir John Lubbock, are all named as probable candidates for the representation of the University.

BAGOT v. BAGOT.

THE celebrated cause of Bagot *v.* Bagot, commenced in April, 1878, in the Irish Probate Court before Judge Warren, has at length terminated in a compromise. The main facts of the case are as follows:—Christopher Neville Bagot emigrated to Australia in the year 1844, and after an absence of some twenty years he returned to England, having amassed a large fortune, amounting to nearly £6000 per annum, invested in land, and some £60,000 of personalty. On August 8th, 1875, he married Miss Verner, he being fifty years of age and she twenty-two, and ten weeks after marriage Mrs. Bagot was confined with a boy. Bagot seemed pleased to have a son, and treated the boy as his own, until March, 1876, when he first seems to have conceived the idea that the child was not his; and in September, 1876, he made a will practically disinheriting Mrs. Bagot's boy, leaving him only some £10,000, and Mrs. Bagot an annuity of £1000 a year, and bequeathing the bulk of his property to his brother. Mrs. Bagot after her husband's decease in May, 1877, brought an action against the executors of the will, on the ground that her husband was not of sound mind when the will was executed. In support of the will, the defendants proved that in 1869 C. N. Bagot was completely paraplegic, the result of injuries in Australia; and that, although he made a fair recovery, he began in the year 1872 to have symptoms of locomotor ataxy. A good deal of evidence was given at the trial by a number of medical men, including Mr. James Teevan, Dr. Habershon, Dr. Poore, Dr. Althaus, Dr. Banks of Dublin, Dr. Gordon of Dublin, Dr. Lockhart Clarke, Mr. Haynes Walton and Mr. Porter of Dublin, to show that locomotor ataxy was well developed in 1873, and continued progressively to get worse until his death, in 1877. All these gentlemen agreed in stating that it was exceedingly unlikely that Mr. Bagot could be the father of Mrs. Bagot's boy, and one went

Digitized by Google

so far as to declare that it was impossible. The medical evidence brought by the defendants was rebutted by that of Dr. C. B. Radcliffe. The jury at the first trial gave a verdict to the effect that Bagot was under a delusion with regard to the paternity of his child, and that when he made his will he was "not of sound mind, memory, and understanding." A new trial was ordered, but on the eve of its commencement the matter was settled by compromise, and Mrs. Bagot's boy will receive £25,000 instead of £10,000, and the bulk of the property will go to the testator's brother, in accordance with the terms of the will.

TEN YEARS' INFANT MORTALITY IN LARGE ENGLISH TOWNS.

IT is now ten years since the improved form of the Registrar-General's Weekly and Quarterly Returns first afforded uniform and detailed mortality statistics relating to twenty of the largest of our English towns. These returns, published during the past ten years, contain an aggregation of statistics bearing upon the rate of infant mortality in these twenty towns, which is full of interest for local sanitary authorities, and indeed for all concerned in the progress of public health. More than two and a half millions of births were registered in these twenty towns during the ten years; and it is scarcely a satisfactory commentary upon the care of infant life in them to know that 171 of each 1000 of the infants born in these towns during the ten years died before reaching the age of one year. In the whole of England and Wales, exclusive of these twenty towns, the rate of infant mortality did not exceed 139 per 1000 during the same period. It is some satisfaction to know, however, that this excess of infant mortality in our largest urban districts is beginning to show a considerable decline; the rate was equal to 179 per 1000 during the five years 1870-4, and declined to 164 in the more recent quinquenniad, equal to a decrease of 9·5 per cent. Infant mortality averaged 158 per 1000 in London, whereas it was equal to 184 in the nineteen provincial towns. On the other hand, the decline of infant mortality was much greater in the provincial towns than in London. Comparing the two most recent quinquenniads, the decline of infant mortality was but 3·7 per cent. in London, whereas it was 12·1 per cent. in the nineteen provincial towns. These figures afford but one of many signs of more successful sanitation in our provincial towns than in our huge and mismanaged metropolis. It will not be without interest to note the average rate of infant mortality during the past ten years in each of the twenty large towns. The rates per 1000 of births, ranged in order from the lowest, were as follow:—Portsmouth 141, London and Brighton each 158, Bristol and Plymouth each 160, Sunderland 166, Wolverhampton 167, Birmingham and Hull each 174, Sheffield 176, Oldham 177, Newcastle-on-Tyne 178, Nottingham 182, Salford 184, Bradford 187, Manchester and Norwich each 188, Leeds 192, and Liverpool and Leicester each 216. The constantly wide difference between the rates of infant mortality in Portsmouth and Leicester (141 and 216 per 1000) during the ten years under notice points to the existence of conditions unfavourable to infant life in Leicester which ought to be determined and removed. Whether the waste of infant life in Leicester be mainly due to causes which may be described as sanitary or social, they are causes distinctly within human control. Medical officers of health, however, constantly deplore their inability to reduce excessive rates of infant mortality; and it is impossible to doubt that in this department of sanitation much good would result from the formation of local sanitary associations, in which the help of educated women might be turned to good account in instructing their less informed and poorer sisters in the necessary improvement in the treatment and management of infants. We have noted that infant mortality has shown a marked decline during the past ten years, which may to some extent be due to the low rate of mortality caused by infantile diarrhœa during the cold summers of 1877 and 1879. The rate of decline, however, although general, was by no means uniform in the different towns. A comparison of the rates in the two past quinquenniads shows that the decline in Bristol and Plymouth did not exceed 1 per cent., and in Bristol 5·4 per cent.; while the decrease was equal to 15·2 per cent. in Bradford, 16·1 per cent. in Newcastle-on-Tyne, 19·6 per cent. in Liverpool, and 20·9 per cent. in Leeds. It is but natural that the largest decline should have occurred in those towns in which the greatest excess prevailed; but it is worthy of note that in Portsmouth, where the lowest rate of infant mortality existed in both the quinquenniads, the decrease in the more recent period was equal to 9·8 per cent. Infant mortality is pretty generally accepted as a sensitive test of sanitary condition, and it may therefore be hoped that statistics bearing on this subject will receive at the hands of health authorities more attention than they have hitherto commanded.

"LOOKING FORWARD" AND "LOOKING BACK."

THE ministry to minds diseased is a distinctly medical function, and there is a "preventive" aspect of medical psychology, not less important than the personal hygiene of the physical life. Nearly all the mental troubles that do not *directly* spring from organic disease—some of which may be reflexly the cause of physical changes in the cerebral and nerve structures they maltreat—are distinctly traceable to the effects of morbid imagining, and nearly all the disorderly mental processes of this class consist in unwisely "looking forward" or "looking back." Hope feeds on the future, and despair is poisoned by the dread of it. The misery of regret and disappointment is a creature of the past. The secret of health of mind and moral integrity consists in taking so firm a footing in the *present* that the mental equilibrium may not be easily disturbed. There is no need to ignore the lessons of the past, or to disregard the objects and obligations of the future, but it should not be forgotten that human life, with its opportunities, its duties, and its responsibilities, is an affair of *now*. We are led to offer this caution and recall the facts to memory because medical science has something to answer for in making men and women miserable by the discovery of incipient disease, which if simply unrecognised might in many instances have been harmless. The mental aspects of clinical practice are, we fear, too often left out of the count.

A LUNACY INQUIRY.

AN inquiry was opened at the White Hart, Brislington, near Bristol, on April 16th, before Mr. Nicholson, Master in Lunacy, and twenty-two jurors, concerning the state of mind of Charles Pierce Melly, formerly of Liverpool, but now an inmate of Dr. Fox's asylum at Brislington. The inquiry was promoted by Mrs. Melly, the wife of the alleged lunatic, who was represented by counsel. Mr Melly conducted his own case, and in so doing effectually convinced the jury (after three days) that he was insane and incapable of managing his own affairs. The history of Mr. Melly's case, as elicited at the inquiry, was interesting and instructive. It appears that he had been a merchant in Liverpool, and was noted for his sound judgment in matters of business and his successful speculations. In the year 1878 he became rather reckless in money matters, quarrelsome with his friends, and otherwise eccentric. In July, 1879, he became possessed by delusions as to assassins haunting him, imagined himself a member of a secret society, and carried a revolver loaded with cotton-wool and butter, which he fired upon a person who came to serve him with a writ.

Digitized by Google

He was placed in the Liverpool Asylum in July, 1879, and transferred to the Brislington Asylum in the following month. The unhappy gentleman's conduct while examining and cross-examining witnesses was marked by much flippancy, sharpness, occasional wittiness, and now and then by violent expressions and actions. Notwithstanding his occasional sallies of mental sharpness, the jury had little difficulty in coming to their decision, and, but for the conduct of the lunatic himself, the inquiry would not have extended beyond one sitting. At one stage of the proceedings the patient caused much amusement by putting on the counsel's wig and gown, and refusing to part with them until a policeman was brought to try the effect of official persuasion.

TESTIMONIAL TO DR. THOMAS ANDREWS, F.R.S., OF BELFAST.

IN December last a committee was formed to obtain funds for the purpose of commemorating the retirement of this gentleman from the vice-presidency of the Queen's College, Belfast, and up to the present close on £1400 has been promised or received. It has been determined to place a portrait of Dr. Andrews in the institution with which he was for so many years identified, and, should the subscriptions permit it, to found a Scholarship in the college in connexion with chemical science. For these objects a sum of about £3000 will be required, and we have no doubt that the application of the committee for the remaining half of the necessary amount will be successful. Dr. Andrews formerly held the post of Professor of Chemistry in the Queen's College, Belfast, and, as our readers are no doubt aware, is a chemist of world-wide fame, having made some most important discoveries in connexion with this branch of science. It was at first uncertain whether a bust or portrait of Dr. Andrews would be presented to the college; but the subscriptions for the latter have been sufficient, and an artist has already been engaged to carry out the wishes of the donors in this respect.

SCARLET FEVER.

TWO reports have been issued by the Local Government Board—one by Dr. Thorne Thorne on an extensive outbreak of scarlet fever in Mr. Barnardo's village home for destitute girls, Barkingside, Romford, the other by Dr. H. F. Parsons on recent prevalence of scarlet fever in, and the general sanitary condition of the Bedlingtonshire Urban Sanitary District, Durham. In Mr. Barnardo's home, between the 28th December, 1879, and the end of the second week of February, 1880, not less than 159 cases of scarlet fever occurred among a population all told of about 440. The outbreak was singular in its mildness, not one fatal attack having occurred. Dr. Thorne writes in the highest terms of the sanitary conditions under which the children reside, and of the general excellent state of their health. The source of the original infection was not obvious, but it seems probable that it was derived from a parcel of clothing sent by way of gift to the Home from a family which had had scarlet fever within it. The earlier cases were so slight as to excite no attention, and hence the disease was disseminated largely before its existence was suspected.

Dr. Parsons was called upon to study scarlet fever in Bedlingtonshire under very different conditions. The locality is a colliery district, containing several large villages, which present those indications of sanitary indifference and negligence too generally characteristic of such villages. Here scarlet fever appears to be rarely if ever absent.

The two reports enable us to form a painfully vivid picture of the difficulties which beset a sanitary authority and its officers in their efforts to contend successfully with scarlet fever. In the one case the insidiousness of the infection of the disease in the beginning of the outbreak seems to set at fault preventive measures, however well contrived; in the other case the prospect appears to be equally disheartening from the difficulty of eradicating the conditions which appear to determine the persistent prevalence of the malady in the district. We want more light on the localities of permanent prevalence of scarlet fever in the kingdom and on the conditions determining this permanency there. The subject is one which might well enlist the careful attention of the Medical Department of the Local Government Board, and which deserves that attention.

FRACTURES OF THE NASAL BONES.

IN the March number of the *Annals of the Anatomical and Surgical Society of Brooklyn*, U.S.A., Dr. Mason has published a paper on "Fractures of the Nasal Bones." As a result of experiments on the dead subject he concludes that in all cases of fracture with depression of the nasal arch, the nasal processes of the two superior maxillæ are always broken, and on the same plane. After alluding to the difficulty of successfully treating these cases, and pointing out that the mucous membrane of the nose is so sensitive that it cannot bear the pressure of any cannula or compress sufficiently firm to raise and support the depressed fragment, he suggests a novel procedure of his own. It is to correct the deformity, and then pass a needle across the nose from side to side through the line of fracture. A small piece of ribbon or bandage is then placed across the nose and fastened over the ends of the needle. The needle may be withdrawn about the sixth day. If the line of fracture is not symmetrical, the bones are to be drilled at suitable spots. Unfortunately Dr. Mason omits to state whether he has ever tried his method of treatment.

WALSALL COTTAGE HOSPITAL.

THE Walsall Cottage Hospital, lately the scene of most of the labours and triumphs of "Sister Dora," is likely to become the arena of a contest between a number of the honorary medical officers on the one side, and the lay authorities and a "Sister" on the other. A circular, pointing out some of the defects of the medical management of the hospital, and suggesting appropriate remedies, signed by a large number of medical men interested in the institution, has been addressed to the subscribers. If we may accept the statement of the grievances as true, the recommendations are not only temperately made, but are cogently reasonable. Among other matters it is proposed first, that there shall be a house-surgeon, and that the surgical cases shall be treated by him, and be under his care, subject to the supervision of the members of the honorary surgical staff; second, that the duties of the sister shall be limited to the nursing and domestic departments. Equally just and rational seem to be the proposals, that each of the honorary surgeons be allotted a week for the reception of in-patients, and have assigned to him two days a week for seeing out-patients.

CHARGE OF STARVING.

MISS SCOTT, the keeper of a boys' school at Hastings, has been committed for trial on the charge of endangering the life of her servant-maid, named Hauseman, by giving her insufficient nourishment. Dr. Ashenden and Dr. Parsons were called to see the girl in March last, and they found her, in the house of her mistress, apparently dying of starvation. The emaciation was extreme. There was hectic fever, and the peculiar odour of starvation. She had had convulsions, and there was gangrene of one of the toes. The bed was wet through. The girl was altogether in a horribly neglected state. She has been removed to the workhouse, and has already picked up thirty pounds in

Digitized by Google

weight, although still too ill to attend before the magistrates to give evidence. Some details were given as to the amount of food provided for the inmates of Miss Scott's establishment, but these were inconclusive, and the defence is reserved.

THE BRADFORD FEVER HOSPITAL.

MR. RIX, the resident-surgeon of the Bradford Fever Hospital, has introduced a new kind of bath into that establishment, which, in these days of treating fever by cold bathing, bids fair to be a great boon to both nurses and patients. The bath, which used to be in a separate room, is now placed in the centre of the ward, the patients being wheeled up to it in their beds. It is so constructed that curtains can be easily erected and drawn, and privacy be thus secured. When not in use the bath is covered and converted into a table for the patients. The bathing of patients, which previously was attended by considerable difficulty to the nurse and some discomfort to the patient, has now become an easy and comfortable process, one which can be performed at any hour by a single attendant. The idea seems to us to be a good one, provided the waste-pipe and overflow-pipe of the bath have no connexion whatever with the sewers of the hospital.

MR. JOHN SIMON, C.B.

THIS gentleman has resigned his seat in the Council of the Royal College of Surgeons, to which he was elected in July, 1868, in conjunction with Mr. Holden (who now fills the President's chair) and Dr. Humphry of Cambridge. Mr. Simon was re-elected in 1876, and was elected President of the College in 1878. There will now be four vacancies in the Council to be filled up by the Fellows in July next—viz., one caused by the death of Mr. H. Hancock, and the resignation of Messrs. T. B. Curling, F.R.S., and G. Busk, F.R.S.

ON Wednesday, at the sitting of the Court of Appeal, at Westminster, Sir Hardinge Giffard, Q.C., applied to Lords Justices Brett, Cotton, and Thesiger, for an extension of time to enable him to move on behalf of the plaintiff in the action of Howell *v.* West and Jones, appealing from a judgment of the Queen's Bench, refusing a new trial on the grounds that the verdict at the trial before the Lord Chief Justice and a special jury at Westminster was against the weight of evidence, and misdirection. Their lordships granted the application.

THE condition of the public schools of New York appears to be attracting attention just now in that city. Some idea of the extent of the evils existing in those institutions, says *Gaillard's Journal*, "may be formed from the fact that in one school (in East Forty-second-street) at least five per cent. of the teachers are temporarily invalided; many of them suffering from diseases of the eye produced by too strong a light." The laws of health as regards ventilation and cubic space would seem also to be to a large extent ignored.

A MEETING of the Council of the Royal College of Surgeons in Ireland will take place on May 4th, to elect eight Examiners to examine for the Fellowship and Letters Testimonial, three to examine for the diploma in Midwifery, and a similar number to examine students as to their proficiency in General Education.

THE death is announced of Dr. Hamilton, late medical superintendent of the Leeds Union Infirmary. Dr. Hamilton, who resigned his post last year in consequence of illness, was on a voyage to Australia, when he was seized with an attack of congestion of the liver, which rapidly proved fatal. He was aged twenty-nine.

IN the Afghan war despatches, Surgeon J. Duke is mentioned as "conspicuous for his unremitting attention to the wounded under a heavy fire." Amongst the names of officers whose good services Brigadier-General Baker had "great pleasure in recording" appear those of Surgeon-Major C. A. Atkins, A.M.D., and Surgeon J. Lewtas, Corps of Guides.

THE proposed site of the infectious diseases hospital to be erected at Torquay appears to be exciting considerable opposition. Most of the objections urged, however, are such as would apply to any situation of a hospital of the kind with the needful accessibility from centres of population.

THE Lord Lieutenant of Ireland has appointed Mr. S. T. Gordon, A.B. T.C.D., L.K.Q.C.P.I., to be surgeon to the Royal Irish Constabulary, vice Mr. E. Leclerc, resigned. Mr. Gordon is a son of the late President of the College of Physicians of Ireland.

A TELEGRAM from Ekaterinoslav, published by the *Golos*, states that diphtheria is spreading in the Novomoscow district, and that hundreds of children have been attacked by the malady. A detachment of doctors and nurses has been despatched to the affected villages.

THE medical officer of health of Brighton has been instructed by the Sanitary Committee of the Town Council to take proceedings, under the Public Health Act, to compel owners of manufactories to adopt within one month the best means of preventing the emission of smoke from their works.

DR. W. H. BROADBENT will deliver the Annual Oration at the rooms of the Medical Society of London on May 3rd, at 8.30 P.M. The subject chosen is, "The Pulse and some of its Indications."

THERE is no foundation for the statement that diphtheria is epidemic at Chelmsford gaol. A single case occurred a few weeks ago, but probably the disease was contracted outside the establishment.

AMONG the candidates for the post of Medical Officer of Health for the Port of London are the following:—Dr. Domett Stone, Mr. Mantle, and Dr. Benjamin Browning.

A BILL has been introduced into the Californian Legislature to prohibit the payment of percentages on prescriptions to physicians by druggists.

THE accident to Dr. C. H. H. Sayre, to which we referred last week, has, we regret to state, terminated fatally.

IT is proposed to apply for a Government loan for the purpose of building an infectious disease hospital at Chatham.

THE vestry of Bangor have at last decided to establish a local Board of Health for the town.

MEDICAL EDUCATION IN INDIA.

WE have received, through the Surgeon-General of Bombay, copies of five addresses delivered by his Excellency Sir Richard Temple, the Governor of the Presidency—three of them to the native students at the Grant Medical College in 1878-79 and -80, and two to the students at the Medical Schools at Poona in 1878 and 1879. They are interesting as showing the progress which medical education is making in India, the views held respecting it by so able an administrative authority, and the practical interest he has taken in so important a subject.

From these addresses we learn that at the Grant College

Digitized by Google

two standards of medical education were recognised—the higher, for the licentiate and M.D. degree; and the lower comprising two branches, the apothecaries' class and the hospital assistants' class. The instruction in the hospital assistants' classes was given in the vernacular. The period of study for the higher stand extended over five, and for the lower over three years. During the famine in Bombay the want of subordinate medical officers was greatly felt; and, with a view to increase their numbers, it was then decided to create two medical schools—one at Poona and the other at Ahmedabad—for hospital assistant vernacular classes, which were thereafter to be discontinued in the Grant Medical College. The school at Poona was opened in 1878 and that at Ahmedabad in 1879, and both seem to give promise of answering the purpose for which they were created. The Grant College is now devoted entirely to the education of students for the higher standard. In his first address to the students, in 1878, Sir Richard Temple sketched out the intended changes above noticed, and justified the course adopted by Government of extending the lower standard of medical education by the circumstances of the country, the lamentable deficiency of educated medical practitioners, and the duty of saving the people from "the tens of thousands of quacks of various sorts and denominations who are obtaining employment," and to whom the native population naturally apply in the absence of qualified practitioners. "Unless we provide a proper and adequate medical staff and sufficient strength for the whole Presidency, we shall still leave the sick people at the mercy of those empirical remedies, of those quack medicines, of those remains of barbarous and antiquated superstitions which still exist in this country." Sir R. Temple looks forward to the period—apparently still far distant—when it will be possible to introduce into India laws to prevent the practice of medicine by unqualified persons. In the concluding portion of his address Sir Richard adverted to some of the weak points of the students, and inculcated upon them the necessity of acquiring promptness and decision in applying practically the theoretical knowledge acquired in the schools—firmness and nerve, combined with delicacy and precision of handling in surgery—courage and self-reliance in confronting prejudices, combating with ancient superstitions and bearing the frowns of their countrymen, and in fearlessly exposing themselves in the way of duty to the risks of infection and contagion—and, above all, enthusiasm in their work, the enthusiasm of humanity in preventing disease and assuaging suffering.

In his second address, delivered in 1879, Sir R. Temple took up the subject of preventive, as distinguished from curative medicine, and stated that it was probable that by comprehensive measures "80,000 deaths annually might be prevented, or rather deferred," in the Bombay Presidency. He dilated at some length upon the importance of hygienic education; registration of vital statistics; purification of the water-supply; examination of food, of air, and of dwellings; conservancy, including drainage; utilisation of sewage; sanitary engineering; vaccination; and prevention of contagious diseases; and impressed upon the students the necessity for continuing their studies of these important subjects after leaving the college.

In his third, and farewell address, Sir Richard, having on previous occasions discussed curative and preventive medicines, and, as he conceives, exhausted these topics, gave a brief *résumé* of the leading introductory lectures delivered at the principal medical schools in London in 1877–78 and 79, as reported in THE LANCET. Marking "the lofty tone, the comprehensive thoughtfulness, the moral earnestness, the philanthropic enthusiasm, and the truly religious sentiment by which they are pervaded." It appeared to him that the opinions expressed in them might with great advantage be brought under the notice of the students in the Grant College, and were well worthy of their thoughtful consideration.

It is gratifying to learn on such authority that medical education is receiving so much attention from the Government, and making such satisfactory progress in India. It is also matter for congratulation to find that so able an administrator and so hardly-worked an official as Sir R. Temple can find time, and has the inclination to direct his energies to the promotion of so important an object. A careful perusal of these addresses makes us feel regret that their author did not succeed in securing his election as a member of the new Parliament, where his services might have been of much value alike from his knowledge of Indian affairs and from the interest which he evidently takes in the promotion of sound medical education.

GENERAL LIBRARY University of MICHIGAN

HEALTH OF LARGE ENGLISH TOWNS

SIXTEENTH WEEK OF 1880.

THE excessive death-rates which have very generally prevailed in our large towns since November last have now declined, and the rate of mortality has fallen below the average. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5510 births and 362 deaths were registered last week. The births exceeded by 325, while the deaths were 213 below, the average weekly numbers during 1879. The deaths showed a further decline of 205 of those returned in recent weeks, and were equal to an annual rate of 21·3 per 1000, against 24·9, 22·5, and 22·7 in the three preceding weeks. During the past three weeks of the current quarter the death-rate in these towns has averaged 22·2 per 1000, against 26·3 and 26·0 in the corresponding periods of 1878 and 1879. The lowest death-rates in the twenty towns last week were 13·6 in Portsmouth, 13·7 in Leicester, 19·0 in Brighton, and 19·6 both in Leeds and Bristol. The rates in the other towns ranged upwards to 24·9 in Norwich, 25·0 in Sunderland, 27·5 in Salford, 28·8 in Nottingham, and again the highest rate, 32·0, in the borough of Plymouth. The fatality of epidemic measles in Plymouth showed a further increase last week.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 445 and 449 in the two preceding weeks, were 455 last week. They included 132 from whooping-cough, 108 from measles, and 107 from scarlet fever. The annual death-rate from these seven diseases averaged 3·2 per 1000 in the twenty towns, and ranged from 1·5 to 1·6 in Brighton and Leeds, to 6·3 and 13·9 in Nottingham and Plymouth. Measles showed the largest proportional fatality in Plymouth, Nottingham, Oldham, and Sunderland; and scarlet fever in Sheffield, Norwich, and Salford. Eighteen more deaths resulted from measles in Plymouth, making no less than 231 recorded within that borough since the middle of November last. Nine more deaths were referred to fever, principally enteric, in Sheffield. Small-pox caused 15 more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had slowly increased from 167 to 178 in the three previous weeks, further rose to 187 on Saturday last; forty-eight new cases of small-pox were admitted to these hospitals during last week, against 42 and 44 in the two previous weeks. The Highgate Small-pox Hospital contained 26 patients on Saturday last, a further increase upon recent weekly numbers.

The fatality of lung diseases, which has shown so constant an excess during the past few months, is now rapidly declining. The deaths referred to diseases of the respiratory organs in London, which had been 395, 365, and 348 in the three previous weeks, further declined to 295 last week, and were 84 below the corrected average; 176 resulted from bronchitis, and 90 from pneumonia. The annual death-rate from diseases of this class was equal to 4·2 per 1000 in London last week; the rate from the same diseases in Liverpool was 6·2 per 1000.

THE ADELAIDE HOSPITAL, DUBLIN.—The annual meeting of the friends of this charity was held on April 20th. The report stated that the new buildings were opened in October last. The institution now practically consists o two distinct hospitals, the main building with the Madeleine wing being used for non-infectious medical and surgical patients, while a separate and isolated hospital has been erected for fever cases. These improvements have involved a large expenditure, so that a considerable debt has been incurred, and it has been found necessary to restrict the admissions to a less number of patients than the institution is capable of accommodating. This condition of things the committee trust the increased liberality of their fellow-townsmen will enable them to amend.

"Audi alteram partem."

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—Your remarks in THE LANCET of April 3rd, on the difficulty of procuring genuine Chian turpentine, and pointing out the unfavourable results which must occur in the treatment of cancer by the use of a spurious drug, appeared very opportunely; and I have reason to know that they were well received by the profession and the public, and that they effected the desired purpose by causing the profession to be specially solicitous to procure the genuine article. I regret, however, to find from numerous letters sent to me by medical men requesting my opinion as to the genuineness of drugs supplied to them, that it is necessary to further caution the profession against the practice of some druggists, who supply either a wholly factitious article, or a Chian turpentine adulterated with some other resin of an inefficient and sometimes of an injurious description.

Of the large number of specimens sent to me not more than five per cent. had any pretensions to be genuine. Some pills guaranteed to be prepared from the genuine drug were also submitted for my approval, and I found them to be prepared either from Venice, or strained crude turpentine. I have also had numerous letters from medical men asking to be informed whether a peculiar irritability of the skin with other symptoms resembling those of acute urticaria, were incidental to the administration of the remedy, and also inquiring as to the best method of treating the complication, and the means of preventing it, as it interfered materially with the progress of the treatment. Other patients having derived no benefit from a remedy given, although fairly tolerated, it was proved that they were not taking the genuine turpentine. I may state that I have never found the symptoms above-mentioned to be produced by the administration of the genuine remedy, and I have no hesitation in stating that when they do appear they are an indication of an impure drug being given. The violet-like odour of the urine always becomes manifest on the administration of the impure drug, but I believe that it is invariably absent when the genuine drug is taken. If there is odour of the urine at all, it is much milder, and of a more fragrant character.

It is self-evident that the substitution of an impure drug has a tendency to bring the treatment into discredit, besides being a positive cruelty to the patients. It is possible that the lavish supply of the impure article at extravagant prices may have arisen from ignorance on the part of the druggists of the properties of true Chian turpentine, as I am unwilling to believe that their commercial morality is so lax as to induce them deliberately to substitute an impure turpentine for the pure article.

I may add that, as the purity of the drug is an essential condition of successful treatment, I cannot hold myself responsible for the validity of many of the trials which are now being made, nor can I admit that they constitute a fair test of the new method of curing cancer.

I am, Sir, yours, &c.,

Birmingham, April 27th, 1880. JOHN CLAY.

To the Editor of THE LANCET.

SIR,—On 27th March, 1880, you published a most interesting article upon the Treatment of Cancer of the Female Generative Organs by a new method, which method appears to be by the internal exhibition of Chian turpentine. Pereira makes the obtaining of this drug as exceedingly problematic. Fifty years ago, in the drug market, it was seldom ever seen, yet it was rarely sold as a *manufactured* article on the spot, mostly Venice turpentine being one of the articles used, in its spurious manufactory. I have been lately obliged by a letter from Horner and Son, by Mr. Bowdas, dated April 5th, 1880, to the effect that no true Chio was to be had. There is a great demand for it, and the firm had written abroad for some. I procured some very old Chio turpentine, and Professor Rodgers supplied the following analysis:—

Resin and volatile matter	98·06
Ash, after burning	1·94
Composed of	
Silica	·78
Alumen, iron, and silicate of iron ...	·029
Lime	·52
Residuum, chiefly fine sand	·62
	1·949

Mr. Kensington, in his Compilation of Analyses, gives the *ash* of the seed of the Strasburg turpentine, or the Abies picea, as follows:—

Potash	21·75
Soda	6·76
Magnesia	1·67
Lime	1·54
Phosphoric acid	39·65
Silica	11·71
Peroxide of iron	1·31
Chloride of sodium	·57

Both these analyses show silica in considerable quantity, and if it cannot be procured in sufficient amount, I recommend in its place the use of the Strasburg turpentine.

In 1874 I published in the *Edinburgh Medical Journal* a short essay upon the medicinal properties of silica in cancer, &c., having had considerable experience in that disease. I only had one case which responded to treatment so quickly as Professor Clay's, but the patients have been well two, four, and ten years, with no return. The real efficacy of silica lies, however, not in its promoting *cure*, but in its giving freedom from *pain*. Now and then it cures, not always, and located in any part; but on true medullary cancer it appears to have little power, except that it appears to change somewhat the character of its structure first. The form I employ is that of lozenges, and by their being artificially prepared, I, of course, know how much resin, lime, silica, &c., each contains, but given in organic preparations the amount is very uncertain.

I will conclude this letter with a short extract:—"The quantity of silica, when used artificially, being two grains in the twenty-four hours, is much larger than that introduced by drinking two or more pints of Messisquoi or Bethesda waters daily. But it must be borne in mind that iron or sulphur, taken as natural chalybeates or alterative waters, give much greater results than the same ingredients and the same proportions prepared artificially, probably because they are more soluble and better adapted to enter into the circulation when prepared naturally than they are when prepared artificially; but however the matter is explained, about the result there can be no doubt; that a one-tenth part supplied from Nature's laboratory is equal to *one* part prepared artificially."

I am, Sir, your obedient servant,

South Belgravia, April 7th, 1880. RICHD. F. BATTYE.

THE CROTON-OIL TREATMENT OF RINGWORM.

To the Editor of THE LANCET.

SIR,—I have read with much interest Mr. Alder Smith's and Mr. Cottle's communications on the treatment of ringworm by croton oil. No doubt the system of producing inflammation in the skin by counter-irritants sufficient to overcome the pre-existing disease is a good one, and was taught by the late Mr. Startin many years ago, but I think these gentlemen carry their treatment almost too far, for I have seen cases of ringworm in which croton-oil liniment, carbolic acid, oleate of mercury, and other powerful irritants, have produced most painful sores and nasty ulcerations. Indeed, I have had a few cases brought to me in this state, and I cannot help thinking the treatment is somewhat heroic to young patients.

In some hundreds of cases of ringworm that have come under my notice the last few years, I find that much milder irritants will, I may say always, effect a cure, no matter how chronic the disease, and some I have seen of years' duration yield to a simple and careful treatment. For instance, careful washing the scalp night and morning with soft soap, and, if there

Digitized by Google

is already suppurative inflammation, soft soap mixed with yelk of egg, and the nightly inunction of an ointment of white precipitate, twenty or thirty grains to the ounce of vaseline or benzoated lard; and, in the more chronic cases, daily brushing into the roots of the hair a modified "Coster's paste" (composed of iodine pigment, three drachms; creasote, half an ounce; oil of cade, half an ounce) is always effectual, at least in all the cases I have had to treat, and I do not know that I have lost sight of many that were not quite relieved.

Dr. Alder Smith desires to draw attention to the "efficiency of the croton-oil treatment in the production of kerion as a certain and speedy cure in the most inveterate forms of the disease." It would be interesting to know how soon a cure is effected by this treatment. I find it is a difficult thing to give a certain prognosis of cure under *two* or *three* months at least—that is to say, the complete destruction of the parasite, and a healthy growth of new and sound hair.

I am, Sir, yours truly,

Sackville-street, April 26th, 1880. JAMES STARTIN.

To the Editor of THE LANCET.

SIR,—As Mr. Smith's letter in reference to the above subject, in this week's LANCET, may possibly lead to misapprehension of the principles of treatment of ringworm I have endeavoured to indicate, may I be permitted to repeat that an essential part of my plan is that in certain conditions of chronic ringworm, it is advisable to produce an inflammation involving the tissues at least to the depth of the hair-follicles. To be one of the means of effecting this a crop of pustules must fulfil the conditions named in my letter in THE LANCET of April 17th.

I am, Sir, your obedient servant,

WYNDHAM COTTLE, M.B. Oxon., F.R.C.S.

Savile-row, W., April 24th, 1880.

TRANSVERSE DEPRESSIONS ON THE NAILS.

To the Editor of THE LANCET.

SIR,—The note that you recently published, giving an account of an instance of arrested nutrition of the nails during illness, was brought to the notice of a gentleman who having himself afforded an example of this curious appearance, has sent me an account of his own case. Although not a medical man his description is careful, and affords evidence of accurate observation.

In August, 1878, when forty-nine years of age, he was seized with a severe illness; he was unconscious for three days, his life being despaired of, but eventually he made a good recovery, being in bed only for a month. Shortly after the attack it was observed that there was a groove on all the nails, both of the hands and the feet, neither the patient nor those about him having ever heard previously of such an occurrence. The foot marks disappeared first, but the lines on the hand-nails were not cut away until nine months had elapsed. The length of time occupied by the marks on the foot-nails until they advanced to the edge of the nail was not noted. My correspondent informs me that he has a good circulation, that he usually covers his feet warmly, but does not cover his hands, and that his nails and hair grow with unusual slowness.

The points to be noted in this case are first, the fact that the groove on the nails of the hand may persist for nine months (an unusually long time, so far as our present data teach us) before it is finally lost; and secondly, that, contrary to what Dr. Beau leads us to look for in such cases, the mark on the toe-nails disappeared first.

I am, &c.,

Queen Anne-street, W., April 13th, 1880. G. THIN, M.D.

"HERPES GESTATIONIS."

To the Editor of THE LANCET.

SIR,—The cases of "Herpes Gestationis" narrated by Dr. Stanley Gale in THE LANCET for April 17th appear to illustrate some points of interest in the physiology of the reproductive system.

In each instance the eruption began to appear shortly before delivery (three or four days); recurring with several pregnancies. It may be regarded as precisely analogous to—indeed is in some respects identical with—eruptions which in many women almost invariably precede the menstrual flow: they are the ectodermic manifestations which in a more or less pronounced manner accompany menstruation; and they exemplify the grand law of periodicity which pervades that function.

These dermic changes may aptly be likened to the moulting of birds, and other of the lower creatures; indeed, being sexual, they are truly analogous. Every woman who menstruates displays more or less epidermic change at the "periods;" and if closely observed will show either (*a*) increased pigmentation of the skin and its appendages—e.g., freckles, areolæ of nipples, hair—or a little acne, herpes, urticaria, eczema, or altered sweat (ectodermic), or (*b*) coryza, bronchial catarrh, or mucous flux from the bowel, with, in rare cases, casts: (endodermic). (Parenthetically it may be said that casts of the bowel are met with about nine times more frequently in women than in men.)

This and other kindred, but as yet imperfectly observed or understood, points relating to the physiology and pathology of menstruation, I hope, with your permission, to discuss more at large in your pages through my course of systematic lectures about to be delivered.

I have the honour to be, Sir, your obedient servant,

ALFRED WILTSHIRE, M.D., F.R.C.P.

Wimpole-street, W., April 19th, 1880.

RELIGIOUS LIBERTY IN TURKEY AND IN ENGLAND: A CONTRAST.

To the Editor of THE LANCET.

SIR,—Will you allow me to make a few observations on the letter of "J. B. B.," under the above heading in your impression of April 24th.

In the first place I would observe that religious equality was first proclaimed in Turkey in 1839 in the Tanzimat, but the declaration (repeated in 1856) has always remained a dead letter, which "J. B. B." would find to be the case were he a rajah. But the cases cited are not parallel. King's College never did proclaim religious equality. It was established on religious principles, just as University College and the London University were established on secular principles.

I am sure that Mr. Tweedy would find no Government post barred to him on account of his religion, whatever that may be. If such were the case he would have a just cause of complaint, and might then compare the declarations of the Sublime Porte (untruthful as they are) with the practice of the British Government.

I am, Sir, yours, &c.,

Athenæum Club, April 27th. HUMPHRY SANDWITH.

SALICYLATE OF QUININE.

To the Editor of THE LANCET.

SIR,—For the benefit of those who are wishful to try the effects of the above in rheumatism, I append a formula (of my own), which I have used with benefit for some time:—Salicylic acid, one drachm; disulphate of quinine, ten grains; simple syrup, one ounce; strong liquor ammoniæ, one drachm; water, to twelve ounces. The mode of mixing to be adopted is as follows: put the acid and quinine together into the phial, with about eight or nine ounces of water, agitate briskly for a few seconds, let the mixture stand a little while uncorked, then add the liquor ammoniæ, again agitating, then the syrup and the remainder of the water. A few drops more of the ammonia may be required to get a perfectly clear solution. I have found the addition of tincture of digitalis at times advantageous.

I am, Sir, yours truly,

JOHN DEARDEN, F.R.C.S.

Church, near Accrington, April 7th, 1880.

THE LONDON HOSPITAL.—The committee representing employés of the Great Eastern, London, Tilbury and Southend, and North London Railways announce that the next annual ballad concert, in aid of the funds of the London Hospital, will take place at St. James's Hall on Tuesday, May 4th next.

Obituary.

DR. HEATON, F.R.C.P., OF LEEDS.

VERY many of our readers will have shared the sincere regret with which we announced the death of Dr. John Deakin Heaton, after a very brief illness, in the 63rd year of his age.

On the afternoon of March 24th he attended a meeting of the committee of the Yorkshire College, but left before the business was concluded. Feeling cold, he walked quickly to another public meeting, but still complained of chilliness, and went home to bed suffering, as was soon ascertained, from an attack of pneumonia, to which he succumbed at five o'clock on the morning of March 29th. During the brief period of this last illness he was attended by the principal members of the profession in Leeds, including Dr. Eddison, Dr. Allbutt, Dr. Barrs, (house physician at the General Infirmary), and Mr. Pridgin Teale.

Dr. Heaton was a native of Leeds, and was educated at the Grammar School there, and subsequently at the Leeds School of Medicine and at University College, London. At the former of these institutions he gained five medals in as many different subjects, and in the latter the same number of prizes, including the gold medal in Medicine and the Fellowes gold medal for Clinical Medicine. He also carried off the silver medal awarded by the Apothecaries' Company for Botany—open, as our readers are aware, to all medical students. In the examination for the M.B. of the University of London he obtained the gold medal in Botany and other honours, and in the M.D. examination in 1849 he received the gold medal for the best commentary on a case in medicine, and the "Certificate for Special Proficienoy in Medicine." In 1842 he spent some time in Paris, attending the medical practice of the hospitals, and after a long Continental tour he commenced practice in Leeds, where he thenceforth continued to reside.

Thus qualified, it was but natural that he should early become associated with the Medical School of Leeds; he first lectured there on Botany, then on Materia Medica, and subsequently on the Practice of Medicine—the last for more than twenty years; and he also held the responsible office of treasurer to the Council of the School, of which he was three times president. He was successively elected physician to the Dispensary and the Fever Hospital—during his connexion with which he had two severe attacks of fever—and to the Leeds General Infirmary. In 1849 he was elected a Medical Fellow of University College, and in 1868 had the honour of becoming a Fellow of the Royal College of Physicians. He was also a Fellow of the Royal Medico-Chirurgical Society and of the Medical Society of London, and was the contributor of various papers to the several medical and literary periodicals.

Besides his professional labours, Dr. Heaton took an active part in most of the educational and benevolent institutions of the town: for four years—1867 to 1870—he was president of the Philosophical Society, and for many years its honorary librarian. He was also Chairman of the Committee of the Yorkshire Board of Education, and member of the first School Board for the borough; as a Justice of the Peace for the West Riding, he was energetic in the magisterial work of his district. He was, besides, a trustee of funds for charitable uses (well known as the "Pious Uses Trust"), was honorary physician to the Tradesmen's Benevolent Institution, to the Unmarried Women's Benevolent Institution, and the Leeds Town Mission; consulting physician to the Women and Children's Hospital; and one of the trustees of several of the livings of Leeds.

But the institution with which Dr. Heaton's name will be the most permanently and gratefully remembered is the Yorkshire College for the Promotion of Science and Literature: from 1869, when, as chairman of the Executive Committee of the Yorkshire Board of Education, he first took up this idea, he steadily worked for the furtherance of the plan, until in 1875 the College was inaugurated, and it is now firmly established as one of the great permanent institutions of the district, having an estate and buildings of its own, and a large staff of able professors. In recognition of these services to education, the Clothworkers' Company of the City of London conferred upon him the honorary membership of their company, and at the same time he was admitted a citizen of London.

The list of the offices and posts of responsibility and honour which he filled prove that there was ample grounds for the high esteem in which Dr. Heaton was held by his fellow-townsmen and the public generally. It may be said, indeed, that he attracted to himself in a singular manner the confidence of those around him; his extensive knowledge and his aptitude in bringing that knowledge to bear, his cultured mind, his great experience, his clearness and soundness of judgment, and the unflagging diligence (one of his special characteristics from boyhood) he showed in discharging any duty which he undertook, making him a most valuable counsellor and assistant in all the matters which were brought under his notice. His loss will be long and greatly felt in connexion with many of the most important public institutions of the district.

The funeral of Dr. Heaton took place on April 2nd, and, under the circumstances which we have stated, it is not surprising that the sad occasion brought together such a numerous gathering of mourners as has rarely been seen at the graveside of one of our *confrères*, for it included not only his personal and professional friends, but great numbers of others, amongst whom were most of the leading inhabitants of Leeds and its vicinity.

EDWARD JACOMB ASBURY, M.R.C.S. ENG., &c.

MR. EDWARD JACOMB ASBURY died on April 1st, 1880, at East Retford, Notts, aged fifty years, from apoplexy. He was the fourth son of the late Jacob Vale Asbury, Esq., surgeon, of Enfield, Middlesex, with whom he was in extensive practice for some years. Afterwards he succeeded to the practice of the late Dr. Allison of Retford, Notts, where he carried on a large and select practice up to the time of his death. He held the appointment of medical officer of health. He gained much experience during the Crimean war, and when at Westminster and Enfield, during a severe epidemic of cholera, was appointed surgeon to a district, which task he performed with unceasing energy and the greatest kindness to the sufferers. His loss is deeply regretted by his patients and a large circle of friends. He leaves five children under age.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were elected Fellows of the College on Thursday last:—

Barlow, Thomas, M.D. Lond., Montagu-street.
Coupland, Sidney, M.D. Lond., Nottingham-place.
Dickinson, Edward Harriman, M.D. Edin., Liverpool.
Donkin, Horatio Bryan, M.B. Oxon., Upper Berkeley-street.
Fox, Cornelius Benjamin, M.D. Edin., Chelmsford.
Goodhart, James Frederick, M.D. Aberd., Weymouth-street.
Kelly, Charles, M.D. Lond., Worthing.
King, Robert, M.B. Camb., Harley-street.
Mahomed, Frederick Henry Horatio Akbar, M.D. Brussels, St. Thomas's-street.
Shaw, Thomas Claye, M.D. Lond., Banstead Asylum, Surrey.
Topham, John, M.D. Lond., Collingham-road.

The following gentlemen having passed the required examination, were admitted Members on the same day:—

Dunbar, James John Macwhirter, M.B. Lond., Ladbroke-grove.
Lubbock, Montagu, M.B. Lond., Foulis-terrace.
O'Connor, Bernard, M.D. Queen's Univ., Brook-street.
Tirard, Nestor Isidore Charles, M.B. Lond., King's College.
Whittle, Ewing Maud Glynn, M.D. Dub., Cambridge.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on April 22nd:—

Barratt, Herbert James, Bedford.
Benson, Alfred, Settle, Yorkshire.
Davis, William George, M.D. Pennsylvania, Philadelphia.
Frampton, T. H., Tewkesbury, Gloucester-terrace.
Hockridge, Thos. Granville, M.D. McGill Univ., Westbourne-pk.
Parkes, Louis Coltman, Weybridge, Surrey.
Perkins, G. C. Steele, Exeter.
Permewan, Arthur Edward, L.S.A., Redruth, Cornwall.
Reid, Norman Macbeth, Croydon, Surrey.
Rowlands, Hugh Pugh, L.S.A., Bryngwyn, Towyn.
Vise, Christopher, Holbeach, Lincolnshire.
Wheeler, Albert, L.S.A., Southsea, Hants.
Whiting, John, Beccles, Suffolk.

Digitized by Google

Of the 74 candidates examined during last week, 44 passed to the satisfaction of the Court and obtained their diplomas; 5 passed in Surgery, and when qualified in Medicine will be admitted Members; the remaining 25 failed to reach the required standard, and were referred for six months' further professional study. Eight candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical degree or licence recognised by the College, were also admitted Members.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at Meetings of the Board of Examiners on April 26th, 27th, and 28th:—

John R. S. Robertson, William B. Benjafield, George A. Atkinson, James G. Houseman, Bernard L. Mills, James D. Dunlop, Edward B. C. Walker, Herbert H. Ashdown, Ernest E. Maddox, John L. Gibson, and Samuel Macken, Edinburgh; Charles H. Evers and Charles S. Blair, Newcastle-on-Tyne College of Medicine; Thomas H. Williams and Charles S. Young, Glasgow; William H. Wilcock, Anthony A. Ward, John H. Naylor, William J. Waddington, and George F. S. Arthy, Leeds School of Medicine; William E. Bradley, John Rodley, William H. Winder, and Herbert E. Edlin, Owens College, Manchester; Frederick A. Saunders and William A. Martin, Liverpool; Henry L. Jones, Cambridge and St. Bartholomew's Hospital; William W. Banham and George R. Beardmore, Sheffield School of Medicine; George J. Myles, Bristol; Frank J. Allen, Cambridge; Daniel Riordan, Queen's College, Galway; G. N. Cornish, King's College; John F. Bolton, John Hoole, M. Carrington Sykes, and Robert W. Jalland, St. Bartholomew's Hospital; George T. Lee and Ernest F. Grose, University College; Frank T. Rampton and John H. Spitsly, St. Mary's Hospital; Hugh Heald, Liverpool; Alfred de Winton, Guy's Hospital; Thomas Taylor, Middlesex Hospital; Arthur de C. Sloan, Westminster Hospital; John Oxford, St. Thomas's Hospital.

UNIVERSITY OF DURHAM.—At the Easter Term, 1880, the following gentlemen passed the First Examination for the degree of Bachelor of Medicine, held at the College of Medicine, Newcastle-upon-Tyne, on April 19th, 20th, 22nd, and 23rd:—

Baker, John Hopper.
Brett, James, M.R.C.S., L.S.A.
Coley, Frederic Collins, L.R.C.P., M.R.C.S.
Hamilton, George Clarendon.
Lee, Henry Boynton.
Mears, Frederick Charles.
Mears, William Pope, M.R.C.S., L.S.A.
Robinson, Alfred.
Rowell, Robert Henry.
Sheppard, William John.
Smith, William Harvey, M.R.C.S.
Wheatley, Arthur William.

Four candidates were referred in all subjects. One candidate was referred in Botany, and one in Chemistry.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on April 22nd:—

Breach, James Henry, Yattenden, Newbury, Berks.
Gibbs, Alfred Napier Godby, Clifton, Bristol.
Morris, Edgar Freeman, St. Owen's-street, Hereford.
Pitman, William Weston, Acacia House, Highgate.
Spackman, Henry Robert, Pennfields, Wolverhampton.
Thomson, Thomas, Approach-road, Victoria-park.

The following gentlemen on the same day passed the Primary Professional Examination:—

George Milner Cole, St. Bartholomew's Hospital; Joseph H. Surtees Sumner, London Hospital.

At the Preliminary Examination in Arts held at the Hall on April 23rd and 24th, 137 candidates presented themselves, of whom the following passed and received certificates of proficiency in General Education:—

FIRST CLASS (in order of merit).—1st: T. H. Fisher. 2nd: Mary Emily Dowson. 3rd: W. Lansdale. 4th: E. H. O. Little and Arthur William Jones. 6th: Edward Felix, H. J. Hawthorn, and J. Martyn.

SECOND CLASS (in alphabetical order).—F. W. Abbott, B. Badcock, J. S. Batchelor, G. H. Bate, G. P. Batt, N. J. N. Bray, Samuel J. Brooks, F. St. John Butler, C. Burland, H. L. Cade, J. W. Cafferata, J. S. Coakey, H. W. Chambers, J. C. Christie, W. A. Clarke, John Crisp, F. Evered, R. C. Featherstone, W. J. Fern, Octavius S. Fisher, H. Fox, C. B. Francis, R. Freeman, G. F. C. Gardiner, J. Girvin, T. W. Gibbard, C. B. Gilson, W. H. Godfrey, W. H. Hall, F. W. Hamp, C. J. Heath, T. S. Heaton, A. B. Holberton, W. J. Hosford, W. W. Howard, H. L. Hudson, W. A. Jacobson, T. G. Lavie, J. L. Lewis, G. C. Macdonald, A. A. Macfarlane, J. G. Mackay, F. W. Metcalfe, Anne Emily Mills, W. A. Musbet, F. Nuttall, R. Pinhorn, R. H. F. Routh, Agnes Russell, D. S. Saunders, F. A. Saw, Albert W. Smith, Cecil Smith, J. Baker Smith, Robert E. Smith, Sophia Emilia Smith, C. F. White, J. R. Williams, W. R. Wolfe, Edwin P. Wright, Sydney C. E. Wright, and R. B. Wyeth.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following gentlemen passed the Final Examination for the Surgical qualification at the April examination:—

Hodge, James, Dundee.
Stewart, James, Kirkintilloch.
Young, Patrick R., Bebington.

The following passed the First Professional Examination:—James Gillies, John Humphreys, David Forsyth, Archd. S. Macphail, Henry Jones, John Aitken, Sheridan Dean, Charles Jackson, and John S. Forrest, all of the Glasgow School; Jos. Givan, Belfast School; Jos. H. Wallis, Dublin School.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following passed the Final Examination for the Edinburgh and Glasgow Double Qualification at the examination held on April 12th and following days:—

Brandreth, Charles L., Blackpool.
Thornley, Joseph, Bolton.
M'Ilwraith, Samuel, Glasgow.
Wallace, Robert, Glasgow.
Hyrons, Ernest Augustus, Glasgow.
Milroy, James, Glasgow.
Peck, John Huntly, Glasgow.
Passanha, Vincent Adolphe, Dublin.
Till, George William, Glasgow.

The following passed the First Professional Examination for the Double Qualification at the April examination:—

G. B. Buttery, Ed. A. Cook, James Gilroy, Charles A. Gray, M. H. Guest, John Lyon, John Macdonald, A. R. Mathieson, Henry Oakes, and A. W. White, all of the Glasgow School.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners recently held the undermentioned obtained the Fellowship of the College:—

Banks, Samuel Henry (Surgeon-Major).
Potter, Henry (Surgeon-Major).

ALDERMAN WHITAKER, M.D., has been placed on the Commission of the Peace for the borough of Belfast.

FLEET-SURGEON W. PATRICK has been appointed to the *Britannia*; Staff-Surgeon T. Browne to the *Royal Adelaide*.

DR. SHELTON, Principal Medical Officer at the Garrison, Halifax, Nova Scotia, is about to vacate that post, having received orders to proceed to Aldershot.

A COMBINED meeting of the North Western, Northern Counties, and Yorkshire Associations of Medical Officers of Health will be held in Leeds, on Friday, May 7th.

ON Wednesday evening the thirty-fifth annual dinner of the German Hospital at Dalston was held at Willis's Rooms, the Duke of Connaught presiding. The subscriptions announced were about £3650.

AT the quarterly meeting of the Naval Medical Compassionate Fund, held on the 13th instant, Dr. H. J. Domville, C.B., Inspector General, in the chair, the sum of £70 was distributed among the various claimants.

THE thirty-second anniversary of the City of London Hospital for Diseases of the Chest was celebrated on Wednesday at the Cannon-street Hotel, under the presidency of Mr. C. T. Ritchie, M.P., when the subscription list amounted to about £3000.

THE Local Government Board have notified to the Local Authorities their intention to issue an order for the amalgamation of the township of Bredbury and Romiley, in the Stockport Union, for Local Government purposes, from the 29th of September next. This is in answer to a requisition from the people of Romiley, who were otherwise unable to obtain efficient means of drainage and water supply.

EARLSWOOD ASYLUM FOR IDIOTS.—The friends of this excellent institution held their thirty-third annual festival on April 22nd. The Earl of Rosebery presided over a large and influential company on the occasion. It is satisfactory to learn that the asylum, which contains 565 inmates, collected from all parts of the kingdom, is now free from debt. Subscriptions to the amount of £2047 were announced by the secretary in the course of the evening.

UNIVERSITY OF LONDON.—The following examiners for 1880-81 were elected at a meeting of the Senate held on Wednesday:—Practice of Medicine: W. H. Dickinson, M.D.; and C. Hilton Fagge, M.D. Surgery: John Cooper Forster, M.B.; and Prof. John Wood, F.R.S. Anatomy: Prof. John Cleland, M.D., and Prof. Redfern, M.D. Physiology: Philip Henry Pye-Smith, M.D., B.A.; and Prof. J. Burdon-Sanderson, M.D., LL.D., F.R.S. Obstetric Medicine: J. M. Duncan, M.D., LL.D., F.R.S.E.; and Henry Gervis, M.D. Materia Medica and Pharmaceutical Chemistry: Prof. E. B. Baxter, M.D.; and F. T. Roberts, M.D., B.Sc. Forensic Medicine: Prof. Ferrier, M.D., M.A., F.R.S.; and Thomas Stevenson, M.D.

Digitized by Google

ROSTREVOR WATER SUPPLY.—A scheme for the water supply of this town has been approved of by the Local Government Board for Ireland, and the works will be commenced without delay.

ROYAL HOSPITAL FOR INCURABLES.—The annual festival of the friends and supporters of this hospital was held on April 23rd. A new wing has been built at one end of the building, and it is proposed to erect another wing at the opposite end. At present the number of inmates is 183, and of pensioners 419. The cost of maintaining the former was last year a little over £10,000, whilst the pensions amounted to £8000 a-year. The appeal of the chairman resulted in subscriptions amounting to £4300.

SOUTH LONDON SCHOOL OF PHARMACY.—The medals and certificates for the term ending 15th April were presented by the secretary on the 17th April to the following successful competitors:—Senior Chemistry: medal, Mr. Price; certificate, Mr. Carruthers. Junior Chemistry: medal, Mr. Hill; certificate, Mr. Waring. Materia Medica: medal, Mr. Williams; certificate, Mr. Horne. Botany: medal, Mr. Walkley; certificate, Mr. Waring. Pharmacy: medal, Mr. Waring. The secretary's prize, for Organic Chemistry, was presented to Mr. W. Williams.

DONATIONS TO MEDICAL CHARITIES.—Mr. W. C. Jones of the Elms, near Warrington, has given £500 to the Infirmary of that town. The Grocers' Company have given £100 to the North London Hospital for Consumption at Mount Vernon, Hampstead. Messrs. Coutts and Co. have given an additional 30 guineas to the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor. Captain Charles George Hammond, 16th Lancers, of Brighton, bequeathed £150 each to the Lock Hospital and St. George's Hospital. The Duchess of Norfolk has given £100 to Queen Charlotte's Lying-in Hospital. The Charing Cross Hospital has received £100 each from Mr. Philip D. Tuckett and Mr. R. C. L. Bevan.

Medical Appointments.

Intin ations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

ATTHILL, R. C., L.R.C.S.Ed., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer for the Parish of St. Osyth, in the Tendring Union.

BERRY, W., M.R.C.S.E., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Honorary Medical Officer to the Royal Albert Infirmary, Wigan, vice Hart, resigned.

BLYTHMAN, C. S., M.B., C.M., M.R.C.S.E., has been reappointed Medical Officer of Health for the Swinton Urban Sanitary District. £30 per annum.

BOND, W. J., M.B., L.R.C.S.Ed., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 7 District. £15 per annum.

BOULTER. Mr. W. E., has been appointed Assistant Medical Officer for the Workhouse and Infirmary of the Woolwich Union.

BURMAN, J. W., M.D., L.R.C.S.Ed., has been appointed Medical Officer to the Barnsbury District of the Hungerford Union.

CEELY, R., F.R.C.S.E., L.S.A.L., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 8 District. £12 12*s.* per annum.

CHURTON, T., M.D., has been appointed Honorary Physician to the Leeds General Infirmary.

CLARKE, J. St. Thos., M.B., F.R.C.S.E., &c., has been appointed Honorary Surgeon to the Leicester General Infirmary.

CONRY, J. T. C., L.K.Q.C.P.I., has been appointed Medical Officer to the Salford Union Workhouse, vice C. A. Mercier, M.B., resigned.

DALTON, N., M.R.C.S.E., has been appointed Resident Medical Officer to Queen Charlotte's Lying-in Hospital, vice T. L. Browne, M.R.C.S.E., resigned.

DENNY, C. J., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator to the newly-formed District of Blackwater and Eversley. Also reappointed Medical Officer of Health to the Hartley Wintney Union Rural Sanitary Authority.

DE WOLFE, G. H. H., M.D., has been appointed Honorary Physician to the Sheffield Public Hospital for Diseases of the Skin.

DUNSMURE, J., M.D., has been appointed Examiner in Clinical Surgery in the University of Edinburgh, vice T. Keith, M.D., resigned.

HAMES, G. H., F.R.C.S.E., has been appointed House-Surgeon to the Western General Dispensary, vice S. J. Knott, resigned.

HARDWICKE, H. J., M.D., M.R.C.P.E., has been appointed Honorary Physician to the Sheffield Public Hospital for Diseases of the Skin.

HAZARD, J., M.R.C.S.E., has been appointed Honorary Surgeon to the Sheffield Public Hospital for Diseases of the Skin.

HEX, H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Assistant-Surgeon to the City Provident Dispensary and Surgical Appliance Association, vice P. R. Webb, L.R.C.S.I.

HOOPER, C., M.R.C.S.E., L.S.A.L., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 1 District. £18 per annum.

IRELAND, Mr. A., has been appointed Resident Medical Assistant at the Aberdeen Royal Infirmary.

KNOTT, S. J., M.R.C.S.E., L.S.A.L., has been appointed Surgeon-Accoucheur to the Western General Dispensary.

LEE, R., M.R.C.S.E., L.S.A.L., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 6 District. £18 per annum.

LEITCH, J., M.B., C.M., has been appointed Medical Officer of Health for the Holme Cultram Urban Sanitary District, vice Gordon. £20 per annum.

LEVINGE, E. G., A.B., M.B., L.R.C.S.I., L.M., has been appointed Medical and Sanitary Officer of the Lucan Dispensary District, and to the Local Royal Irish Constabulary, &c.

LITHGOW, T. G., L.R.C.P.L., L.F.P.S.G. & L.M., L.S.A.L., has been appointed Medical Officer and Public Vaccinator to the No. 6 District, comprising Farnborough and Cove, of the Hartley Wintney Union, Hampshire.

PALMER, F. C., L.K.Q.C.P.I., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health to the Brigg Local Board, vice Dr. Paterson, resigned.

PARADISE, T. D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Lowton District and the Workhouse of the Leigh Union, vice Brideoake, resigned.

PEARCE, G., M.D., M.R.C.S.E., has been appointed Honorary Surgeon to the Leicester Infirmary.

POPE, E., M.R.C.S.E., L.S.A.L., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 2 District. £15 per annum.

POWELL, J., jun., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Court Star of West Surrey Lodge of Foresters, Weybridge, vice J. J. Sealy, resigned.

RAMAGE, Mr. J., has been appointed Resident Surgical Assistant at the Aberdeen Royal Infirmary.

RYGATE, B. R., M.B., M.R.C.S.E., L.S.A.L., has been appointed District Medical Officer of the St. George's-in-the-East Union.

SPENCER, C., M.R.C.S.E., L.S.A.L., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 4 District. £23 8*s.* per annum.

WHITE, J. R., M.B., L.R.C.S.I., L.S.A.L., has been appointed Medical Officer to the Second District of the Ongar Union.

WILCOX, R. W., M.R.C.S.E., L.S.A.L., has been reappointed by the Aylesbury Rural Sanitary Authority Medical Officer of Health for No. 5 District. £25 10*s.* per annum.

WILLIAMS, W., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Carmarthen Infirmary, vice E. T. Evans, resigned.

Births, Marriages, and Deaths.

BIRTHS.

EDWARDS.—On the 19th March, at St. John's, Antigua, West Indies, the wife of Arthur E. Edwards, M.R.C.S.E., of a son.

GORDON.—On the 20th ult., at Amersham-road, New-cross, S.E., the wife of John Gordon, M.D., of a daughter.

HARDING.—On the 20th ult., at North Lawn, Westgate-on-Sea, Kent, the wife of G. Clarence Harding, M.R.C.S.E., L.R.C.P.Ed., & L.M., of a daughter.

LANCASTER.—On the 22nd ult., at Lewisham High-road, S.E., the wife of H. F. Lancaster, M.D., of a son.

MARRIAGES.

MILLER—DUNCAN.—On the 21st ult., at Littlegill Farm, Lesmahagow, by the Rev. James Arthur Gray, Free Church, Lesmahagow, assisted by the Rev. James M. Cruickshank, St. Rollox U.P. Church, Glasgow (brother-in-law of the bridegroom), John Miller, M.D., of Springburn, Glasgow, to Ellen Wilson, youngest daughter of the late John Duncan, Esq., Farmer, of Littlegill.

PATTISON—JOYCE.—On the 29th ult., at St. Martin's-in-the-Fields, by the Rev. Richard Westhorpe, Edward Seton Pattison, M.R.C.S.E., L.R.C.P.Ed., to Minnie, eldest daughter of Walter Joyce, Esq.

DEATHS.

BROWN.—On the 24th ult., at 64, Lyndhurst-road, Peckham, London, Helen Agnes Daisy, only child of Dr. William Brown, of Dunedin, New Zealand, aged 6 years.

FERGUSSON.—At 48, Claremont-square, William Edward Laing Fergusson, M.D., after a few hours' illness. Friends will please accept this intimation.

GOURLAY.—At his residence, 1, Victoria Buildings, Weston-super-Mare, Frederick Gourlay, M.D., in his 45th year. Friends will kindly accept this intimation.

HAMILTON.—On the 8th February, on board the s.s. *Garonne*, near Adelaide, Alexander McLeod Staveley Hamilton, M.D., M.R.C.S.E., late Medical Superintendent of the Leeds Union Infirmary, aged 29.

HEATH.—On the 22nd ult., at Doverscourt, Essex, Edward Heath, M.D., R.N.

HENRY.—On the 8th ult., at his residence, Claremont Cottage, St. Helier's, Jersey, James Henry, Esq., M.D., Staff-Surgeon, Royal Navy, aged 61. R.I.P.

LLEWELLYN.—On the 10th ult., at 152, Whitechapel-road, Llewellyn Llewellyn, M.D. St. And., M.R.C.S.E. & L.S.A.L., aged 60. Interred in the family vault.

MOYLAN.—On the 20th March, on board H.M.S. *Euphrates, en route* to India, W. J. Moylan, Surgeon, A.M.D., son of J. Moylan, Esq., of Rathkeale, co. Limerick, in his 32nd year. Buried at sea. Sincerely mourned by his sorrowing widow and friends.

RUSSELL.—On the 19th ult., at High-street, Lurgan, Philip Crampton Russell, M.D., aged 70.

SAYRE.—On the 11th ult., Charles Henry Hall Sayre, M.D., eldest son of Lewis A. Sayre, M.D., aged 29.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE HEALTH OF STONEHOUSE.

THE medical officer of health for Stonehouse (Mr. T. Leah) reports that the mortality in his district, for the first quarter of the present year, was at the rate of no less than 53·20 per 1000 of the inhabitants per annum. This arose from the exceptional prevalence and great mortality of an epidemic of measles, common to Stonehouse and the conterminous towns of Plymouth and Devonport. As the measles began to subside, a sudden and very general outbreak of diarrhœa among adults occurred. Mr. Leah's report, as it appears in the *Western Morning News*, does not throw any light upon the sources of the exceptional prevalence of measles and of the outbreak of diarrhœa. Quite half of the mortality from measles, it is stated, occurred among children of Marines. This at least would seem to call for some official inquiry into the location and sanitary administration of the Marine establishment there.

House-Surgeon.—It is very unfair; but fees are not usually paid for the attendance of house-surgeons as witnesses at inquests on persons dying within the walls of hospitals.

PERSISTENT VITALITY OF THE UMBILICAL CORD.

To the Editor of THE LANCET.

SIR,—About a month ago I was requested to see a baby, three weeks old, suffering from this very curious condition. The nurse informed me that the ligature used at delivery and the piece of cord (on its distal side) had fallen off about the usual time, but there were no signs of the cord separating at the navel. The child suffered great pain, and for the last few days had cried almost without ceasing. On examination, I found a fleshy outgrowth, fully an inch long, projecting from the umbilicus. It was quite rigid, with a raw granulating appearance, bleeding on the slightest touch, and extremely sensitive, and there was a small central depression at its free extremity. The nurse stated that she had to change the dressing frequently on account of a watery oozing from it. The urine, however, was passed *per vias naturales* in normal quantity. The central depression did not lead into a canal. A strong silk ligature was applied tightly to its base at its junction with the umbilicus. This was attended by some hæmorrhage, as it cut its way through in tightening the knot. Pressure and cotton-wool stopped the bleeding readily, and the latter was left on as a dressing. Next day, on removing the dressing, there was nothing visible but a small thread of dead tissue, which was snipped off with a pair of scissors. In three more days the ligature came away with the dressing, and the navel assumed a normal appearance. The umbilical cord at birth was observed to be unusually thick.

Remarks.—The nature of this case is highly interesting from several points of view: (1) Although the ligature applied at birth had dropped off about the fifth day, the piece of cord on its proximal side had remained attached to the body, become granulated over, and exhibited great vitality. (2) As throwing some light on the much-disputed point of the presence of nerves in the umbilical cord; for it was highly sensitive to the touch, and a source of great suffering to the little one, as evidenced by incessant crying. (3) It is a rare condition, and somewhat allied to a case of patent urachus mentioned by Mr. Bryant, though the difference between the two is important, and at once apparent.

Yours truly,

CHARLES R. WILLIAMS, M.B., C.M. Edin.

Ashby-de-la-Zouch, April 26th, 1880.

Mr. C. J. Stocker.—We are not aware that the precise form of stethoscope has been tried. It would probably be found that the difficulty of maintaining the ear nozzle in position would render it useless, and that, even if successful, it would have no advantage over the ordinary form.

THE POTTER'S FIELD.

IN a notice of the Report of the Board of Health of Louisiana in the *American Journal of Medical Sciences* for April, p. 519, there occurs the following:—

"The bulk of the book is made up of minute reports from the sanitary inspectors of the seven districts in which the city of New Orleans is divided. These records give in detail the facts upon which the generalisations already referred to are founded. It is not, therefore, necessary for us to review them separately, and we will content ourselves with the following indignant protest from Dr. George Holt, of the fourth district, in regard to the pauper burying-ground, the condition of which must go far to account for the dread in which strangers hold the poisonous atmosphere of New Orleans during the summer months:—'This is now the potter's field, a low marsh wherein the sexton performs his heavy task faithfully and as best he can, sometimes floating to their graves the dead and weighting them into their homes, the whole graveyard being often a foot under water. The nature of his field renders it impossible for him to dig these graves deeper than has been his habit. But this is potter's field—an injurious infliction and an outrage upon the living, a disgrace to our humanity, to our morals, and to our city; an indecency perpetrated upon the dead *because they died poor!*"

Volunter Surgeon.—The legal aspects of the case can only be properly considered by a lawyer. We assume that there were sufficient data for the statement, so that its substantiation need not be difficult. As the memorial was a joint one, the signatories may of course reply collectively. A reporter may attend any public meeting.

P. S. F. — We are not aware of any legal objection to a practitioner taking the office of local "registrar of births and deaths," although he may hold certain union appointments.

SIMPLE DISLOCATION OF THE ASTRAGALUS (REDUCED).

To the Editor of THE LANCET.

SIR,—I was on the point of reading the letter in your impression of April 17th on this injury, when I was called to see a young woman, aged about twenty, who had fallen and hurt her foot. She was descending a flight of steps when she fell, and her foot twisted under her. I found that she had sustained a simple dislocation of the body of the astragalus forwards from off the os calcis, and from under the tibia and fibula. The front part of the foot was twisted inwards; some movement of the foot upon the leg could be obtained. The head of the astragalus apparently remained in the concavity of the scaphoid; but the posterior part of the bone or body turning on the head, as on a pivot, was displaced forwards and outwards. The outer edge of its saddle-shaped facet formed a sharp prominence about an inch and a half in front of the external malleolus; beneath this was felt the facet for the fibula, and behind this again the sharp concave edge of the posterior and external facet for the os calcis. When the patient was under chloroform, the astragalus was quite movable in this abnormal position. There was considerable swelling of the soft parts, and some bruising of the skin over the sharp bony prominence. The woman was taken into the hospital under Mr. Humphry. Chloroform was at once administered, and after some manipulation I was able to replace the bone. It returned to its normal position with a sudden jump and a peculiar "crunching" noise, audible at a distance of several feet.

The case seems to me to differ from those usually recorded, in that the head of the bone remained in position, that neither the astragalus nor the foot was fixed, and in the ease with which the dislocation was reduced.

Your obedient servant,

JOHN C. UHTHOFF, M.D. Lond.,

House-Surgeon to the Sussex County Hospital.

Brighton, April 20th, 1880.

To the Editor of THE LANCET.

SIR,—The letter of your correspondent, Mr. Gore, recalls to my mind a case of simple dislocation of the astragalus which occurred to me in March, 1869, but which in the hurry of work I failed to report.

W. H——, a man, aged fifty, was driving a sow, which would run across the road in front of a horse and cart. He drove the sow on, and then tried to step back out of the way, but, failing to get quite clear, the wheel passed over the front of his left foot, he falling on his back, while the foot was held in this position. I was driving past at the time, and had the man carried home, about 2000 yards distance. On examination, the shape of the foot was so peculiar as to leave no doubt as to the nature of the injury. The absence of the heel, together with projecting bone on the instep, with the skin tightly stretched over it, showed clearly the outline of the astragalus. There was intense pain, but no swelling. I made the man lie down, and hug his thigh as tightly to him as possible. Then standing at his foot, I made firm extension on the heel with both hands, while with my thumbs I pressed firmly on the astragalus. With the second attempt it went back to its place with a loud snap. I bandaged the foot, and applied cold, but little effusion took place. Two nights later, hearing that the sow was littering, he could not resist coming down and attending upon her the whole night, without any bad result, however, and in three weeks he was walking about as usual.

I may add that a very good "sucking pig" formed a not inappropriate first instalment of the doctor's fee.

Your obedient servant,

April 19th, 1880. MARTINDALE C. WARD, M.D., &c.

AN ANTIDOTE TO CARBOLIC ACID.

DR. GENFTLEBEN states that sulphuric acid is a good antidote to carbolic acid, entering into combination with it, and forming an innocuous compound. His formula is dilute sulphuric acid, 10 grms.; mucilage of gum arabic, 200 grms.; simple syrup, 30 grms. A tablespoonful of this mixture to be given every hour. Carbolic acid is unfortunately so often taken in error, even in spite of its powerful odour, that there will be abundant opportunities of testing the value of this recommendation.

"A GOOD EXAMPLE."

To the Editor of THE LANCET.

SIR,—In your last week's issue you draw attention, under the above heading, to a recent resolution of the Council of the Royal College of Surgeons in Ireland against indirect advertising by members of the profession, and no doubt the regulation, if carried out, would be advantageous. I may also suggest that a resolution might also be adopted by the same body which would not be out of place, to the effect that meeting homœopathists in consultation was contrary to the dignity of the Licentiates and Fellows of the College. *Verbum sapienti.*

Your obedient servant,

April 27th, 1880. F.R.C.S.I.

TAPEWORM IN THE LUNGS.

AT a late meeting of the Philadelphia Academy of Natural Sciences, Dr. H. C. Chapman described the lungs and liver of a monkey which were completely disintegrated and filled with cysts produced by an immature form of tapeworm. The animal had belonged to the collection in the Philadelphia Zoological Gardens.

M.R.C.S.—Superintendent registrars of births, deaths, and marriages are appointed by the guardians of the poor of each union or registration district; the clerk to the guardians has, however, a prescriptive right to the appointment. The emoluments of the office arise from fees.

Mr. J. M. Kennedy.—Dunglison's (Messrs. Churchill).

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions on Anatomy submitted to the 154 candidates at the primary examination for the diploma of Membership of the College on the 23rd April, when they were required to answer four, and not more than that number, out of the six questions, between the hours of one and three o'clock:—

1. Describe the first rib, naming the structures in immediate relation with it.
2. Describe the ligaments connecting the skull with the spinal column.
3. Describe the coverings and coats of the testicle.
4. Give the dissection necessary to expose the posterior tibial artery; describe its course and relations, and name its branches and their anastomoses.
5. Describe the pelvic fascia in the male, its attachments, arrangement, and relations.
6. Describe the course, relations, and distribution of the musculo-spiral nerve.

The following were the questions on Physiology submitted to the candidates the same day, and with the same conditions, between the hours of four and six o'clock:—

1. Describe an act of deglutition, mentioning in the order of their action the muscles engaged, and their nervous supply.
2. Describe the structure of a lobule of the lung. State the changes which the air and blood respectively undergo in respiration.
3. Describe the conditions requisite for the performance of a simple reflex act. Give examples of reflex acts occurring without sensation, and of others associated with sensation; in each case specifying the several parts concerned.
4. Give the physical characters of urine. What are its normal constituents? State the circumstances which cause variations in them within the limits of health.
5. Describe the structure of a Graafian follicle, and give the changes that take place in it after the discharge of an ovum.
6. How may the function of a nerve be determined? What are the functions of the first four cerebral nerves?

THE QUALITIES OF SEA-WATER AS A POTATION.

To the Editor of THE LANCET.

SIR,—The non-arrival of the training-ship *Atalanta*, with its freight of over 300 lives, and the horrible suspicion that if the ship floats, its living freight is suffering the agonies of thirst from an insufficient supply of water, lead me to address you this note on the important question, How far can life be supported in extreme cases by sea-water? Every year the same pitiful tale is told of shipwrecked sailors, supplied with food, dying of thirst. "Water, water everywhere, and not a drop to drink." Can this be possible? Hoping that you may agree with me in thinking that the question is worth sifting in a scientific journal like THE LANCET, I venture to raise it.

Tales of "castaways" abound with cases of water privation, in which men who have resisted the temptation to drink salt-water have survived; whilst those who have yielded have *speedily* paid the penalty with their lives, dying generally in an outburst of delirium or suicidal mania. So have said the survivors. But it must be remarked that, granted their intelligence, the survivors were not in a fit state to make accurate observations at the times referred to. The main facts, delirium and death, can be easily accounted for in other ways. Exhausted men, moved by the terrors of approaching death, and exposed freely to the chill night winds and noon-tide sun by turns will often die delirious without the intervention of salt-water. Nor, under any circumstances, is it clear why sea-water should act as a *rapid* poison. Not much can be gained from a consideration of the facts of the case as related by survivors broken down in mind and body.

Sea-water is practically of the same composition throughout the world. A specimen taken from the Bay of Bengal, and analysed by Surgeon-Major H. King, M.A., Professor of Chemistry, Madras, was found to contain 3·325 parts of salts per cent. by weight. A specimen taken from the English Channel, and analysed by Schweitzer, contained 3·523 parts per cent. of salts. Subjoined are the analyses in full. To save space the salts are denoted by their symbols:—

	Sodic chlor. $NaCl$.	Pot. chlor. KCl.	Mag. chlor. $MgCl_2$.	Mag. sulph. $MgSO_4$.	Calcic sulph. $CaSO_4$.	Cal. carb. $CaCO_3$.	Cal. brom. $CaBr_2$.	Water. H_2O.
English Channel ..	27·06 ..	0·76 ..	2·66 ..	2·99 ..	1·40 ..	0·08 ..	0·03 ..	964·77
Bay of Bengal ..	26·06 ..	1·20 ..	2·81 ..	1·82 ..	0·36 ..	.. ..	.. ..	966·75

Leaving calcic sulphate and carbonate out of the question as being inert, potassic chloride and magnesic bromide as being insignificant in amount, it will be seen from the foregoing that there are only three salts to be considered—viz., common salt, magnesic sulphate, and magnesic chloride. A pound of sea-water would contain, according to the Channel, or strongest analysis, 188 grains of common salt, 25 grains of magnesic chloride, and 20 grains of magnesic sulphate. These quantities are not in a theoretical sense injurious. Ten times the amount of magnesic sulphate, found in a pound of sea-water, would be considered an ordinary purge. Magnesic chloride is also purgative, but freely diluted, as in sea-water, in much larger quantities than 25 grains. And 188 grains of common salt are less than the average amount excreted from the human body daily. Numerous experiments made in England and France shew that the amount of salt daily excreted, under ordinary circumstances, varies from 175 grains to 274 grains. A certain amount of the salt ingested is decomposed and used up in the system, the chlorine going to the formation of chlohydric acid, required for stomach digestion, and the sodium helping to preserve the balance of density in the fluids of the body. Moreover, some amount of common salt is retained in the body; in the blood, 100 parts of the ash of which contains 54·7 parts of common salt, and in the intestinal tract, in which sodic chloride exerts a most necessary antiseptic and anthelmintic action. It is probable, in view of the foregoing, and of the excretion daily of an amount of salt averaging 225 grains, that over 400 grains of salt should be taken daily to supply the normal wants of the system. This is about the amount consumed from all sources daily by a well-fed person. In the French army the ration of salt is 0·5 ounce, in the navy 0·77; in the Russian army it is 1·59 ounce. But exceptionally large quantities of salt may be taken without hurt. It is no rare thing to give young children for several days together large doses of table salt, in addition to that in their ordinary food, to get rid of worms. Children so treated do not fail in health. For that matter there do not appear to be any cases of the poisonous action of common salt on record, if we except tales of shipwrecks. Nor does it seem likely that the magnesic salts taken with common salt, in the proportions given, can be very injurious. In many parts of India, where the people evaporate salt-water in shallow clay basins exposed to the sun, and scrape up and eat habitually the whole of the product as common salt, no ill effect worth mentioning is observed. These people, it must be supposed, from their method of salt manufacture, eat larger quantities of magnesic chloride and sulphate daily than are found in a pound of sea-water. On the seaboard of Ireland it is a common practice for the peasants to drink a large mug of sea-water every morning for the "good of their health"; they also boil their potatoes in sea-water, and get the full benefit of the magnesic salts both ways, with robust health.

The *Journal de la Société de Médecine de Caen et de Calvados* published some time ago, from the pen of M. Juan, an account of the salt-water drinkers of the Oceanic Islands. These remarkable people, who live on the madreporic atolls of the Pacific, such as the Paumoton Islands, where there are neither brooks nor springs, drink *all the year round* brackish well-water, which is nothing but sea-water imperfectly filtered. M. Juan also mentions the case of a ship which went to Mexico in 1838 with troops. The water on board ran short, and was rationed in small quantities. Some sailors consequently began to drink sea-water, but were soon obliged to leave it off. One man, however, persevered until the ship arrived in Mexico. This man never complained of the sea-water; the only difference remarked in him was that he got yellower.

Here are shown theoretical and practical reasons, from which it may be concluded that in extreme cases, given a food supply, such as ship's biscuit, a pound or more of sea-water may be taken daily with a reasonable hope of prolonging life.

I am, Sir, yours faithfully,

JAS. J. L. RATTON, M.D.,

Dublin, April 20th, 1880. Surgeon-Major.

WAKES.

A FEW days ago a man was summoned at the Birkenhead Police Court for neglecting to properly disinfect his house after the occurrence of typhus fever in it. But the defendant proved that disinfection had been attended to, and the case was dismissed. The nuisance inspector, however, in the course of the proceedings mentioned a fact which, if true, shows the danger as well as the folly of the practice of "waking" the dead. He said this was the thirty-first case of typhus fever which had originated in the neighbourhood from the exposure of a dead body at a wake last November.

G. H. P. asks if San Goarshausen on the Rhine is a resort against hay fever? We have been unable to find any information on the subject.

An Aberdeen University Student.—Of course if the true skin is destroyed it cannot be replaced. Repair will be by a cicatrix of connective tissue.

ARSENIC IN SKIN DISEASE.

To the Editor of THE LANCET.

SIR,—Mr. Malcolm Morris's letter in your issue of April 17th, in which he says that "arsenic should never be combined with any other drug....in order to obtain its full therapeutical value," will surprise not a few of your readers.

I am in a position to take a distinctly opposite view, because my practice is in some respects peculiar, attached as I am to a Manchester hospital. Many patients come from towns round about. When from any cause they are ill, lazy, careless, or out of work, a visit to the "club doctor" or to their local infirmary takes the place of one to Manchester. In scores of such cases I find that the medico consulted prescribes for the cough (or what not), and, finding that the patient has been attending the Skin Hospital, gives him, besides, solution of arseniate of potash in water, with the remark that "he will get as much good from that as from anything he will get at Manchester." I have thus, Sir, a large experience of the value of arsenic uncombined, and I unhesitatingly say that not one patient in fifty will gain as much benefit from it as he would if it had been judiciously combined with other drugs. Does it not seem reasonable, as skin diseases are often aided and abetted, if not caused, by functional or structural alterations in various systems other than the cutaneous, that drugs such as liquor potassæ, tincture of capsicum, "or even iron," should be of great use? It is, of course, open for Mr. Morris to reply that he is writing not of benefiting the patient, but "of the full therapeutical value of arsenic." Well, Sir, the subject is sufficiently important for me to hope that some gentlemen of large experience, and whose opinions are of weight, will favour us with their views on this matter. I differ *toto cœlo* from this view of Mr. Morris, and I sum up thus: A patient comes to me suffering from psoriasis. We all know that arsenic is *the* remedy. Mr. Morris would give it alone, while I would combine it with other drugs according to the circumstances of the case. Which is the right view? I pause for a reply. I am no enthusiast in the use of arsenic, but prescribe it about 400 times per annum.

In conclusion, let me remind those interested in this matter of the very uncertain strength of Fowler's solution as sold by wholesale druggists. I have met with five cases of patients suffering from symptoms of arsenical poisoning, who had been taking, or supposed they were taking, arsenic, but from some accident had their prescriptions made up at a different druggist's shop. One last objection to Mr. Morris's dictum is this—viz., patients are all too ready to ask "What is good for such and such a disease?" They already have practically command of chloral, laudanum, chloroform, and chlorodyne. Should the verdict of the profession favour Mr. Morris's view, we must add arsenic.

I remain, Sir, yours truly,

Manchester, April, 1880. H. STANLEY GALE.

M.R.C.S., L.R.C.P., &c.—Apply to the Secretary of the Graduates' Association, Dr. F. E. Pocock, 20, Golborne-road, Upper Westbourne-park, W.

Poor-law Surgeon might write to Dr. Joseph Rogers, whose address is now 33, Soho-square, W.

J. H. W.—We do not know the address.

ECZEMA.

To the Editor of THE LANCET.

SIR,—I shall be obliged if any brother practitioner would suggest some remedy for the cure of eczema rubrum. I have a case in which I have tried everything I know.

Yours faithfully,

April 21st, 1880. M.R.C.S.

FEES FOR MEDICAL EVIDENCE AT INQUESTS.

To the Editor of THE LANCET.

SIR,—Can a coroner compel me, a house-surgeon, to make a post mortem examination, walk to the place where the inquest is held, and remain there for *three* hours while the other witnesses were giving their evidence, then to give my own skilled evidence, and walk back again to hospital without a fee?

Yours faithfully,

W. S. BYRNE, M.B.

Metropolitan Free Hospital, Commercial-street, April, 1880.

*** This is a question which ought to be tried. When the inquest is held *in* the hospital, no fee is given. This is intolerable; but we doubt whether the additional trouble entailed by attending at another place would not give ground for a fee.

TYPHUS IN GREENOCK.

THE medical officer of health (Dr. James Wallace), in his report for the five weeks ending the 3rd April, reports twelve cases of typhus as occurring during that period. One case came from Port Glasgow, and the other eleven were distributed among four families. Six were traceable to cases previously reported on, while five (all in one family) had the disease imported apparently from Largs.

Mr. R. Fullerton.—The announcement is inserted in THE LANCET of April 24th.

"TOBACCO-HEART."

To the Editor of THE LANCET.

SIR,—In your journal for January 3rd I read a letter from the late Dr. Parkes upon tobacco-smoking. In this letter he expresses a doubt as to the evil effects of the use of it. The tenour of that letter leads me to suspect that Dr. Parkes was not thrown in contact with a class of cases which we have in New England, and which, for want of a better term, I have called in the index to my cases (all being, more or less fully, recorded at the time of examination); "Tobacco Heart."

Many years since I satisfied myself that a person could smoke two or three cigars daily for many years, and often without difficulty; but some sensitive natures could not use even that amount without suffering. The majority of smokers are not so abstemious, and the use of five or ten cigars daily will very frequently cause pain and uneasiness about the region of the heart, and, at times, palpitation; these will be the most marked, if not the sole, symptoms complained of. Such patients have no œdema, no marked dyspnœa. They can walk fast around the room without getting out of breath. There are no physical signs save of health; they have none of the congestions of the lungs observable so often when organic valvular lesions exist. Nevertheless, the cardiac pain is so annoying that the patients can hardly be persuaded to believe that there is no organic disease; much less can they be led to believe that tobacco is the sole cause of their trouble, and that the first step to be taken is to give up wholly the use of the stimulant.

Similar, but less striking and annoying, effects are sometimes produced in this country by coffee. I have thought that the stimulating influences of our climate may contribute to this result; for Americans who may take coffee with ease in Europe, often begin to suffer after their return home. Some persons find it impossible to use coffee, even in minute quantities, after once their system has been, as it were, saturated with it. Similar results follow the use of tobacco.

You may ask why I, at this distance from you, undertake to write an answer to Dr. Parkes's private letter. Dr. Parkes I never had the happiness to meet; but we knew one another, and occasionally corresponded, and I always looked upon him as one of your noblest Englishmen. An opinion given by him *meant something*. It seemed to carry weight. If I had seen that letter before Dr. Parkes died, I should certainly have written to him upon the subject. It is for this reason I now send to you.

I remain, respectfully yours,

Boston, U.S.A., March 29th, 1880. HENRY I. BOWDITCH.

Occasional Reader.—1. The London University.—2. Refer to the Calendar.

Subscriber.—We have no reason to believe the contrary; but the question is a legal one.

CASE OF SUPERFŒTATION.

A CASE of an extraordinary character is recorded in *Gaillard's Medical Journal* for April. The author of the narrative is Mr. W. H. Tate, who states as follows:—

"Several years since Dr. D—— was called to attend Mrs. N—— in confinement, whom he found in labour with her second or third child. He delivered her of a healthy male child, which had no signs of deformity except enlargement of the abdomen. The child prospered well, though its abdomen daily increased in size, and at the age of five weeks he was sent for to perform an operation on the child, which he declined doing. About twenty weeks after its birth Dr. D—— was called again in haste; the infant having fallen against a stove whilst amusing itself with playthings, and cut its head considerably. On arrival he found the child dead. The post-mortem revealed a fœtus in the abdominal cavity, which weighed about five or six pounds. Umbilical cord attached to the great omentum, and the head of the fœtus attached to the lower portion of the child's stomach; top of the head extending several inches into the stomach; hair on head of fœtus three or four inches long."

MEDICAL ETIQUETTE.

To the Editor of THE LANCET.

SIR,—I would ask the Editor of THE LANCET whether it is in accordance with strict etiquette for a practitioner who has been called in consultation with the family attendant to supersede him in the charge of the case if the friends become dissatisfied with its progress?—Yours &c.,

April, 1880. VERITAS.

DIAGNOSIS OF RENAL CALCULUS.

To the Editor of THE LANCET.

SIR,—In your impression of April 17th a letter appears from Mr. Barker, on "A means of Diagnosis of Renal Calculus." In this method Mr. Barker has been preceded by the late Dr. Simon, of Heidelberg, who, in his work on the Surgery of the Kidneys, describes a sound on the principle of an exploring trocar for the detection of stone in the kidney.

Yours obedient servant,

Tottenham, April, 1880. E. HOOPER MAY, F.R.C.S.

Medical Diary for the ensuing Week.

Monday, May 3.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.
ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.
MEDICAL SOCIETY OF LONDON. — 8½ P.M. Conversazione. — Annual Oration by Dr. W. H. Broadbent. Subject: "The Pulse and some of its indications."

Tuesday, May 4.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 3 P.M.
ROYAL INSTITUTION.—3 P.M. Mr. R. H. Scott, "On Wind and Weather."
PATHOLOGICAL SOCIETY OF LONDON. — 8½ P.M. The following Specimens will be shown:—Imperforate Anus; Volvulus in an Infant; Complete Necrosis of Lower Jaw, with Cancrum Oris; Diffuse Sarcoma of Liver in an Infant aged three weeks; Ossifying Chondrosarcoma of the Left Femur, with Secondary Growths; Congenital Talipes Varus and Talipes Calcaneus; Tendo Achillis divided in a Case of Pseudo-hypertrophic Muscular Paralysis; Sequel of a Case of Syphilitic Gummata; Kidneys showing the Cystic Degeneration of Adults; Complete Excavation of one Lung; Acute Fatty Atrophy of the Liver; Aneurism of Aortic Arch Rupturing into Trachea; Congenital Syphilitic Ulceration of the Tongue; &c. &c.

Wednesday, May 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.
ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.
KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M
UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.
EPIDEMIOLOGICAL SOCIETY.—7 P.M. Council Meeting.—8 P.M. Surgeon-General John Murray, "On Removal in Epidemic Cholera." — Dr. Lawrence Hamilton, "On the Report of the German Medical Commission on the Outbreak of Plague in the Province of Astrakan in 1879."
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimen: Encephalocele, by Dr. Godson. — Papers: Dr. Braxton Hicks, "On Recording the Fœtal Movements by means of a Gastrograph"; also, "On a Case of Extra-uterine Fœtation; sudden urgent Symptoms; Abdominal Section."—Dr. C. H. Carter, "On two Cases of Extra-uterine Fœtation, with Results."

Thursday, May 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Light as a Mode of Motion: Theories of Light and Colours."
HARVEIAN SOCIETY. — 8½ P.M. Mr. Reeves, "On Rectal Stricture, with special reference to Rectotomy and Twenty-five Colotomies."—Mr. Cripps Lawrence, "On Rickets."

Friday, May 7.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—8 P.M. Evening Meeting.—9 P.M. Professor Flower, "On Fashion in Deformity."

Saturday, May 8.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Professor H. Morley, "On the Dramatists before Shakespeare."

THE

Lumleian Lectures

ON

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.

Delivered before the Royal College of Physicians,

BY WM. ROBERTS, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL MEDICINE TO THE OWENS COLLEGE.

LECTURE III.—PART II.

Modified Casein or Metacasein.—The conversion of casein into peptone does not take place by a direct transformation of the one body into the other. You all know that milk does not curdle or coagulate in the least degree on being boiled, but when milk is subjected to the action of pancreatic extract (provided no alkali is added) it speedily loses this negative property and curdles abundantly on boiling. This coagulation on boiling is most intense a few minutes after the addition of the extract, and it very gradually diminishes in intensity as the action goes on, and ceases altogether at the same time that acetic acid ceases to cause a precipitate. It was moreover found that if the milk was boiled at the period of the greatest intensity of this reaction, and thrown on a filter, the whole of the albuminoid matter of the milk was caught on the filter in the form of curds, and the filtrate showed not the slightest reaction of casein. These reactions revealed the interesting fact that in the transformation of casein into peptone by pancreatic extract, the first step in the process is the conversion of casein into an intermediate body, and that it is this intermediate body which is subsequently gradually changed into peptone. This body may provisionally be called "metacasein," signifying thereby that it is still casein, but in a modified condition. Metacasein is characterised by two reactions, which, taken together, serve to distinguish it from other proteid bodies; it is coagulated by boiling in neutral media, and it is precipitated in the cold by acetic acid. The conversion of casein into metacasein in pancreatic digestion takes place almost suddenly, as is shown by the following experiment, performed on the 3rd December:—Five cubic centimetres of pancreatic extract were added to 100 cubic centimetres of milk, diluted with one-fourth of its bulk of water, and maintained at blood-heat. The first slight, almost doubtful, evidence of coagulation on boiling was perceived in three minutes; in five minutes coagulation on boiling was pronounced; and in nine minutes it had reached its maximum. From this point coagulation on boiling, and precipitation on the addition of acetic acid, diminished in intensity *pari passu* very gradually for a period of two hours, when both reactions finally ceased.

Taking these observations and reactions together, it is evident that the conversion of casein into metacasein constitutes a first and distinct step in the transformation of casein by trypsin, and that this step is antecedent to the further and slower changes by which metacasein is transmuted into peptone. It is impossible not to see in this a striking analogy with the sudden transformation of gelatinous starch into soluble starch under the action of diastase, as described in a previous lecture.

When milk is rendered slightly alkaline by the previous addition of a little bicarbonate of soda, no precipitation on boiling occurs during its digestion by pancreatic extract. But the metacasein is nevertheless produced, and its presence may be detected by carefully saturating the alkali, and then boiling. For although metacasein is precipitated on boiling when the solution is neutral, it is not precipitated when the solution is even slightly alkaline. This is the reason why, in preparing peptonised milk for the sick, it is desirable to add to it a small quantity of bicarbonate of soda.

The foregoing account of the behaviour of milk with pancreatic extract will greatly facilitate the comprehension of the practical rules which must be followed in preparing peptonised dishes for invalids. I confine myself for the present to articles of which the basis is milk, or farinaceous gruel, or both together.

Peptonised Milk.—A pint of milk is diluted with a quarter of a pint of water, and heated to a temperature of about 140° F. (60° C.). Two or three teaspoonfuls of liquor pancreaticus, together with ten or twenty grains of bicarbonate of soda, are then mixed therewith. The mixture is then poured into a covered jug, and the jug is placed in a warm situation under a "cosey," in order to keep up the heat. At the end of an hour or hour and a half the product is boiled for two or three minutes. It can then be used like ordinary milk.

The object of diluting the milk is to prevent the curdling which would otherwise occur and greatly delay the peptonising process. The addition of bicarbonate of soda prevents coagulation during the final boiling, and also hastens the process. The purpose of the final boiling is to put a stop to the ferment action when this has reached the desired degree, and thereby to prevent certain ulterior changes which would render the product less palatable. The degree to which the peptonising change has advanced is best judged of by the development of the bitter flavour. The point aimed at is to carry the change so far that the bitter taste is distinctly perceived, but is not unpleasantly pronounced. As it is impossible to obtain pancreatic extract of absolutely constant strength, the directions as to the quantity to be added must be understood with a certain latitude. The extent of the peptonising action can be regulated either by increasing or diminishing the dose of the liquor pancreaticus, or by increasing or diminishing the time during which it is allowed to operate. By skimming the milk beforehand, and restoring the cream after the final boiling, the product is rendered more palatable and more milk-like in appearance.
